Fabrication and Electrical Characterization of MONOS Memory with Novel High-κ Gate Stack

L. Liu, J. P. Xu*, C. L. Chan, P. T. Lai*

Abstract — A novel high-κ gate stack structure with HfON/SiO₂ as dual tunneling layer (DTL), AlN as charge storage layer (CSL) and HfAlO as blocking layer (BL) is proposed to prepare the charge-trapping type of MONOS non-volatile memory device by employing in-situ sputtering method. The memory window, program/erase and retention properties are investigated and compared with similar gate stack structure with Si₃N₄/SiO₂ as DTL, HfO₂ as CSL and Al₂O₃ as BL. Results show a large memory window of 3.55 V at P/E voltage of +8 V/-15 V, high program/erase speed and good retention characteristic can be achieved using the novel Au/HfAlO/AlN/(HfON/SiO₂)/Si gate stack structure. The main mechanisms lie in the enhanced electron injection through the high-κ HfON/SiO₂ DTL, high trapping efficiency of the high-K AlN material and effective blocking role of the high-κ HfAlO BL.

Keywords: MONOS memory, high-κ gate stack, charge storage layer, tunneling layer, blocking layer

I. INTRODUCTION

The challenges for non-volatile memory devices are to achieve fast program/erase (P/E) speed at low operating voltage, large memory window and good 10-year data retention simultaneously [1]. Because of the advantages in scaling, simple fabrication process and robustness against defect-related leakage, metal-oxide-nitride-oxide-silicon (MONOS) memory devices become attractive candidates [2]. Extensive researches have been performed in recent years, involving the use of high-κ HfO₂ [2-3] or AlN [1], [4-5] as charge storage layer (CSL), the use of Si₃N₄/SiO₂ [2] or ZrO₂/SiO₂ [6] as dual tunneling layer (DTL) to enhance the tunneling current, the use of Al₂O₃ as the blocking layer (BL) instead of SiO₂ [7-8] and the use of high-work-function metal gate [9-10] for suppressing electron injection from gate electrode. However, less work concentrated on combining the advantages of high-κ BL and CSL with the dual high-κ/SiO₂ band-engineered tunneling layer. In this paper, we report a novel high-κ gate stack structure --- Au/HfAlO/AlN/(HfON/SiO₂)/Si for MONOS memory application which combines a new DTL of HfON/SiO₂ with the high-κ HfAlO BL and AlN CSL to comprehensively improve the performances of the devices. The electrical characteristics of this novel device are evaluated through comparison with the similar high-κ gate stack structure of Au/Al₂O₃/HfO₂/(Si₃N₄/SiO₂)/Si. Experimental results indicate that large memory window, fast program/erase speed at low operation voltage and good retention property can be obtained using this novel high-κ gate stack structure.

II. DEVICE FABRICATION

Fig. 1 is the schematic cross-section of gate stack of MONOS memory device. To improve the P/E characteristics of MONOS flash memory device, a new high-κ stack gate dielectric structure of Au/HfAlO/AlN/(HfON/SiO₂)/Si is proposed, with HfON/SiO₂ as double tunneling layer, AlN as charge-storage layer and HfAlO
as block layer, as shown in Table I. These high-κ dielectrics were consecutively deposited in-situ by reactive sputtering (or co-sputtering) method using Denton Vacuum Discovery Deposition System at room temperature. First, a 3-nm thick SiO₂ was thermally grown in dry O₂ at 900 °C on p-type Si substrate with a resistivity of 5-10 Ωcm. Then, a nominal 6-nm HfON was deposited by reactive sputtering of Hf in an Ar/N₂ (24:6) ambient, followed by the deposition of a nominal 10-nm Al₂O₃ by reactive sputtering of Al in an Ar ambient (24 sccm). A post-deposition annealing (PDA) was carried out in N₂ at 700 °C for 60 s to improve the dielectric quality. For obtaining densification and high-quality tunneling layer and especially blocking layer, their deposition rates were set at low values of 0.125 nm/min and 0.1 nm/min respectively. On the contrary, the charge-storage layer was deposited at a higher rate of 2 nm/min so that more deep-level traps can be formed during deposition. For comparison, a normal high-κ gate dielectric stack of Au/Al₂O₃/HfO₂/(Si₃N₄/SiO₂)/Si (as control sample) was prepared using the same deposition procedure, with a nominal 6-nm Si₃N₄ RF-deposited using Si₃N₄ target at a rate of 0.1 nm/min in Ar (24 sccm), a nominal 12-nm HfO₂ RF-deposited using HfO₂ target at a rate of 0.17 nm/min in Ar (24 sccm) and a nominal 10-nm Al₂O₃ RF-sputtered using Al target at a rate of 0.084 nm/min in Ar/O₂ (24/6) ambient. For avoiding the crystallization of HfO₂, the PDA was performed at 500 °C for 120 s in N₂. Finally, the high-work-function Au was evaporated and patterned as gate electrode and then Al was evaporated as back electrode, followed by forming-gas annealing which was completed in H₂/N₂ (5% H₂) for 20 min at 400 °C.

For evaluating the memory window and programming/erasing characteristics, high-frequency (1-MHz) C-V curves were measured using HP4284A precision LCR meter, and the programming/erasing voltages were applied by HP4156A precision semiconductor parameter analyzer. The flat-band voltage was extracted from the measured C-V curves by assuming \( C_p/C_{ox} = 0.5 \) (\( C_p \) and \( C_{ox} \) are the flat-band and oxide (or accumulation) capacitances respectively).

### III. RESULTS AND DISCUSSION

#### A. Memory window and program-erase performance

The memory window is determined from shift of the flat-band voltage which is extracted from the measured C-V curves under different P/E voltages. As can be seen from Fig. 2, the memory window of the novel device at P/E voltages of +8 V/-10 V, +8 V/-12 V, +8 V/-15 V is 2.35 V, 3.15 V and 3.55 V, respectively, and it becomes 0.35 V, 0.75 V and 1.35 V under the same P/E voltages for the control device. The larger memory window even at low program voltage for the novel device than the control device should be ascribed to the high trapping capability of high-κ AIN charge-storage layer [4] and suitable double tunneling layer structure.

The program/erase performances are evaluated in terms of the flat-band-voltage change (\( \Delta V_{fb} \)) by applying a P/E voltage of +/- 10 V or 15 V for 100 μs. As shown in Table II, larger \( \Delta V_{fb} \) is obtained for the novel device than the control device under both the same program voltage and the same erase voltage, indicating higher program and erase speeds for the former than the latter. Since the P/E mechanisms are controlled by FN tunneling, the faster programming is due to the higher K value of HfON than Si₃N₄, which results in higher electric field in SiO₂ and thus enhanced carrier injection from the substrate to the charge-storage layer, and on the other hand, it probably means a smaller \( \Delta E_C \) of HfON-Si than Si₃N₄-Si. The high erase speed is attributed to the effective blocking role of the high-κ HfAIO blocking layer, which reduces the electron injection from the gate into the AIN charge storage layer during erasing, and small equivalent oxide thickness of the HfON/SiO₂ double tunneling layer, which enhances the hole injection from the substrate.

measured after programming or erasing at +15 V or -15 V for 1 ms. The retention characteristic is evaluated by measuring the C-V curves after removing the program or erase voltage for 1 - 10000 s. Obviously, a small $V_{fb}$ variation is observed for the novel device with an initial memory window of 3.35 V, which gives an extrapolated 10-year memory window of 2.1 V. The good retention characteristics are due to the strong Al-N bonds related to better trapping capability [5] and deeper trap levels. Also, the suitable high-$\kappa$ HfAIO blocking layer and HfON tunneling layer, which have reasonable barrier height when contacting with AIN respectively, are responsible for the good retention.

### IV. CONCLUSION

A novel high-$\kappa$ gate stack structure of Au/HfAIO/AIN/(HfON/SiO2)/Si for non-volatile MONOS memory device application is fabricated by in-situ sputtering. Comparing with the Au/Al2O3/HfO2/(Si3N4/SiO2)/Si gate stack structure, the novel device exhibits a large memory window of 3.55 V at a P/E voltage of +8 V/-15 V, high program/erase speed and good retention characteristic with an extrapolated 10-year memory window of 2.1 V. The large memory window is related to the effective AIN charge storage layer with more deep-level traps. High P/E speed is attributed to the suitable HfON tunneling layer with higher k value and small conduction-band offset, and effective blocking role of the HfAIO blocking layer. Good retention property lies in the reasonable barrier-height match between the AIN charge-storage layer, HfAIO blocking layer and HfON tunneling layer.
Therefore, the Au/HfAlO/AlN/(HfON/SiO₂)/Si gate stack structure is a promising candidate for making high-performance non-volatile MONOS flash memory devices.
