The inositol 1,4,5-trisphosphate (InsP₃) receptor (InsP₃R) plays a critical role in generation of complex Ca²⁺ signals in many cell types. In patch clamp recordings of isolated nuclei from insect Sf9 cells, InsP₃R channels were consistently detected with regulation by cytoplasmic InsP₃ and free Ca²⁺ concentrations ([Ca²⁺]ᵢ) very similar to that observed for vertebrate InsP₃R. Long channel activity durations of the Sf9-InsP₃R have now enabled identification of a novel aspect of InsP₃R gating: modal gating. Using a novel algorithm to analyze channel modal gating kinetics, InsP₃R gating can be separated into three distinct modes: a low activity mode, a fast kinetic mode, and a burst mode with channel open probability (Pₒ) within each mode of 0.007±0.002, 0.24±0.03, and 0.85±0.02, respectively. Channels reside in each mode for long periods (tens of opening and closing events), and transitions between modes can be discerned with high resolution (within two channel opening and closing events). Remarkably, regulation of channel gating by [Ca²⁺]ᵢ and [InsP₃] does not substantially alter channel Pₒ within a mode. Instead, [Ca²⁺]ᵢ and [InsP₃] affect overall channel Pₒ, primarily by changing the relative probability of the channel being in each mode, especially the high and low Pₒ modes. This novel observation therefore reveals modal switching as the major mechanism of physiological regulation of InsP₃R channel activity, with implications for the kinetics of Ca²⁺ release events in cells.

INTRODUCTION

Inositol 1,4,5-trisphosphate (InsP₃) is a second messenger generated together with diacylglycerol by phospholipase C activated by G protein-coupled and tyrosine kinase receptors in response to extracellular stimuli (Berridge and Irvine, 1989; Berridge, 1993). The free InsP₃ binds to its receptor (InsP₃R), a ubiquitous, ER-localized Ca²⁺ channel, activating it to release Ca²⁺ from the ER lumen to increase cytoplasmic free Ca²⁺ concentration ([Ca²⁺]ᵢ). InsP₃-mediated [Ca²⁺]ᵢ changes play critical roles in multiple signaling pathways and are involved in generation and regulation of multiple biological processes, including synaptic transmission, gene expression, and apoptosis. Analyses of InsP₃-mediated [Ca²⁺]ᵢ signals in nonexcitable cells have revealed complex spatial and temporal features, providing highly regulated global as well as localized control of Ca²⁺-dependent processes (Woods et al., 1986; Petersen et al., 1991; Tregear et al., 1991; Thorn et al., 1993; Bootman et al., 2002).

Characterization of InsP₃R channel activity and its regulation is essential for molecular insights into these intricate intracellular Ca²⁺ signaling pathways. Application of the patch clamp technique to isolated nuclei (Mak and Foskett, 1994) has provided the most direct approach to study the detailed permeation and gating properties of single InsP₃R ion channels in their native ER membrane environment. The endogenous InsP₃R of cultured insect Spodoptera frugiperda (Sf9) cells shares many basic properties with Xenopus and rat InsP₃R channels studied previously, including a biphasic dependence of its activity on [Ca²⁺]ᵢ, that is critical for generation of spatially and temporally complex [Ca²⁺]ᵢ signals in cells (Ionescu et al., 2006; Foskett et al., 2007). The InsP₃R channel activities observed in Sf9 nuclear patches last longer than the channels in the other systems before they inevitably inactivate (Boehning et al., 2001; Mak et al., 2005; Ionescu et al., 2006). The longer activity durations of Sf9 InsP₃R channels provide more event transitions for gating analyses, enabling observations of novel gating behaviors over longer time scales.

Examination of extensive current records of single Sf9 InsP₃R channels in the presence of well-controlled and constant levels of [InsP₃] and [Ca²⁺]ᵢ, revealed that the channels did not display steady-state gating behavior, but instead exhibited spontaneous changes in gating kinetics through distinct patterns of behavior, or modes. We developed a new algorithm to analyze modal gating kinetics of the channel and identified three distinct

Abbreviations used in this paper: InsP₃, inositol 1,4,5-trisphosphate; InsP₃R, InsP₃ receptor.
gating modes of the InsP3R: a mode in which the channel is mostly bursting, another with fast channel gating kinetics, and one with long quiescent periods, with channel open probability $P_o$ of 0.85, 0.24, and 0.007, respectively. Unexpectedly, the channel $P_o$ within each mode remain relatively consistent over a wide range of $[\text{Ca}^{2+}]_i$, and $[\text{InsP}_3]$. Remarkably, our analysis therefore indicates that the observed biphasic $[\text{Ca}^{2+}]_i$ dependence and $[\text{InsP}_3]$ regulation of InsP3R channel activity are generated primarily by ligand regulation of the relative prevalence of the three gating modes.

MATERIALS AND METHODS

**SF9 Cell Culture and Nuclear Isolation**

*Spodoptera frugiperda* (SF9) cells (Invitrogen) were grown and maintained in SF-9001II serum-free media ( Gibco BRL) in suspension culture according to the manufacturer’s protocols. Each batch of cells was subcultured three to four times before being used for electrophysiology and then propagated and used for nuclear isolation for up to 7–8 wk in culture before a new lot was thawed and expanded. Nuclei were prepared for patch clamping as previously described (Ionescu et al., 2006). The nuclear preparation was added to a standard bath solution in an experimental chamber on the stage of an inverted microscope as previously described (Mak et al., 1998; Boehning et al., 2001). Isolated nuclei (5–10 μM in diameter) were distinguished from intact cells based on their unique morphology and selected for electrophysiology (Mak et al., 2005; Ionescu et al., 2006).

**Data Acquisition**

Nuclear patch clamping was performed as previously described (Mak et al., 1998). To maximize the duration of the observed channel activity, current recording was started as soon as seal resistance exceeded 150 MΩ. The standard pipette solution contained (in mM) 140 KCl, 10 HEPES (pH 7.3 by KOH), 0.5 Na2ATP, 0.5 Ca2+ chelator, and various $[\text{Ca}^{2+}]$ and $[\text{InsP}_3]$, as indicated. The bath solution contained (in mM) 140 KCl, 10 HEPES (pH 7.3 by KOH), 0.5 BAPTA (1,2-bis(2-aminoethoxy)ethane-N,N,N’,N’-tetraacetic acid; Molecular Probes), and 0.225 CaCl2 (free $[\text{Ca}^{2+}] = 300$ nM). All solutions were carefully buffered to desired free $[\text{Ca}^{2+}]_i$ and $[\text{InsP}_3]$, as indicated. The model previously developed to quantitatively account into InsP3R channel gating kinetic parameters like channel $P_o$ or open or close to closed channel durations observed. The channels sometimes remained closed for extensive periods (seconds to tens of seconds) that were orders of magnitude longer than other closing durations (∼10 ms). In addition, the transitions of InsP3R channel gating from one mode to another occurred abruptly (Fig. 1). To avoid inherent limitations of conventional modal gating analysis algorithms, we developed a novel algorithm that is able to (a) determine when modal transitions occurred with high temporal resolution, and (b) identify the gating modes of InsP3R channels in current records of arbitrary durations without the requirement to average channel kinetic parameters like channel $P_o$ or open or closed channel durations (Appendix).

**Characterization of Modal Gating**

To characterize this modal gating of the SF9 InsP3R channel and its regulation by $[\text{Ca}^{2+}]$, and $[\text{InsP}_3]$, we examined thousands of seconds of single-channel current records that were obtained in many experiments in the presence of saturating (10 μM) and subsaturating (33 nM) $[\text{InsP}_3]$, and subactivating (0.1 μM), optimal (1 μM), and inhibitory (89 μM) $[\text{Ca}^{2+}]$ (Table I). One characteristic of InsP3R channel gating is the wide range of closed channel durations observed. The channels sometimes remained closed for several hours (seconds to tens of seconds) that were orders of magnitude longer than the mean closed channel duration (∼10 ms). In addition, the transitions of InsP3R channel gating from one mode to another occurred abruptly (Fig. 1). To avoid inherent limitations of conventional modal gating analysis algorithms, we developed a novel algorithm that is able to (a) determine when modal transitions occurred with high temporal resolution, and (b) identify the gating modes of InsP3R channels in current records of arbitrary durations without the requirement to average channel kinetic parameters like channel $P_o$ or open or closed channel durations (Appendix).

Our modal gating analysis algorithm uses insights into InsP3R channel gating derived from an allosteric model previously developed to quantitatively account for single InsP3R channel gating behaviors under a wide range of $[\text{InsP}_3]$ and $[\text{Ca}^{2+}]$: that open InsP3R channels close either via brief ligand-independent closings or via closings with durations regulated by $[\text{InsP}_3]$ and $[\text{Ca}^{2+}]$. (Mak et al., 2003). Because the ligand regulation of InsP3R channel gating is of primary interest, burst analysis was used (Magleby and Pallotta, 1983a) in the channel gating analysis to remove the majority of the brief ligand-independent channel closings so that kinetics of the ligand-dependent channel gating can be more easily discerned (Appendix and Table II therein). After burst analysis, the remaining channel openings and closings should be predominantly due to ligand-regulated channel gating. For clarity, those channel openings are referred to as the endogenous InsP3R in its native ER membrane environment over a wide range of concentrations of cytoplasmic ligands ($\text{InsP}_3$ and $\text{Ca}^{2+}$) (Ionescu et al., 2006). With rigorous control of constant ligand and ionic conditions in the pipette and bath solutions during our experiments (Ionescu et al., 2006), we found that in all ligand conditions used, the InsP3R exhibited apparent modal gating behaviors: it gated with steady kinetics for extensive periods (significantly longer than the mean open and closed channel durations) before gating abruptly changed into a discernibly different pattern. In experiments yielding single InsP3R channel current records, channels were regularly observed to exhibit many such transitions through several modes of gating kinetics (Fig. 1).

**RESULTS**

Application of the nuclear patch clamp technique to nuclei isolated from cultured insect SF9 cells provided long, uninterrupted single-channel current records of
bursts with durations $t_b$ separated by burst-terminating gaps with durations $t_g$.

Based on the values of $t_b$ and $t_g$ of adjacent burst-gap pairs, our algorithm consistently identified three distinct gating patterns (modes) in all the InsP$_3$R channel current traces obtained in all $[\text{Ca}^{2+}]_i$ and $[\text{InsP}_3]$ examined (Appendix). In the gating mode with high $P_o$ (H mode), the channel exhibits mainly bursting behavior with only brief gaps interrupting the long bursts of channel activity (Fig. 2, A and D). In the gating mode with intermediate $P_o$ (I mode), the InsP$_3$R channel gates frequently with mostly short openings and closings (Fig. 2, B and E). In the low-$P_o$ (L) mode, the channel has long closed periods interrupted with brief, infrequent openings, so channel $P_o$ is very low (Fig. 2, C and F).

channel duration ($\tau_o$) over more than an order of magnitude as [Ca$^{2+}$] was changed, while mean open channel duration ($\tau_i$) remained relatively constant in all [Ca$^{2+}$], (Fig. 3 E).

Examination of the gating properties of the InsP$_3$R channel during the periods in which the channel remained in a particular gating mode revealed that the channel $P_o$ within each gating mode ($P_o^M$, with M standing for H, I, or L) has a distinct value 0.85 ± 0.02, 0.24 ± 0.03, and 0.007 ± 0.002 for the H, I, and L modes, respectively, that remains surprisingly consistent over all [Ca$^{2+}$] examined (Fig. 3 B). Because the modal gating analysis algorithm assigns modes only by the values of $\tau_o$ and $\tau_i$ after burst analysis, without directly taking into account the channel $P_o$ (Appendix), the consistency of the channel $P_o^M$ over the various ligand concentrations strongly suggests that the gating modes detected are true representations of the gating kinetics of the channel and not an artifact of the analysis protocol.

Because the InsP$_3$R channel $P_o$ within a mode ($P_o^M$) exhibited relatively small [Ca$^{2+}$] dependencies, [Ca$^{2+}$], must regulate the overall channel $P_o$ predominantly by regulating the fraction of time the channel spends in the different gating modes (relative prevalence $\pi^M$) (Fig. 3 C). Examination of modal kinetics revealed that $\pi^H$ is comparatively [Ca$^{2+}$] independent (Fig. 3 C); the frequency of the channel entering the I mode (relative modal frequency $\pi^I$) (Fig. 3 D) as well as the mean modal dwell time $\langle \tau_i \rangle$ of the channel in the I mode (Fig. 3 J) exhibited very little [Ca$^{2+}$] dependence. In contrast, both $\pi^H$ and $\pi^I$ showed profound ligand dependencies. In the presence of saturating 10 $\mu$M InsP$_3$ and optimal 1 $\mu$M [Ca$^{2+}$], the InsP$_3$R channel is found most of the time in the H mode with high $P_o^H$, and in the L mode for relatively little time (Fig. 3 C), resulting in the observed high overall channel activity (Fig. 3 A). The high $\pi^H$ observed is due to the channel entering the H mode more frequently (higher $f^H$, Fig. 3 D) and staying in that mode longer (higher $\langle \tau_i \rangle$, Fig. 3 J). In nonoptimal [Ca$^{2+}$], (0.1 and 89 $\mu$M), the channel has low overall activity (Fig. 3 A) mainly because it enters the L mode more frequently (higher $f^L$, Fig. 3 D). Unlike $\langle \tau_i \rangle$, which exhibits a strong [Ca$^{2+}$] dependence, $\langle \tau_i \rangle$ remains within a relatively narrow range in all [Ca$^{2+}$], (Fig. 3 J).

Although InsP$_3$R channel $P_o^M$ stayed within a narrow range over all [Ca$^{2+}$], examined, the gating kinetics within a mode are not [Ca$^{2+}$], independent. The channel open, closed, burst, and gap duration distributions in the three modes ($\langle t_o^M \rangle$, $\langle t_i^M \rangle$, $\langle t_b^M \rangle$, and $\langle t_g^M \rangle$, respectively) all exhibited statistically significant variations over the [Ca$^{2+}$], range examined (Fig. 3, F–I).

**[InsP$_3$]** Regulation of Modal Gating

InsP$_3$R channel gating is regulated by [InsP$_3$] as well as by [Ca$^{2+}$]. It has been established that [InsP$_3$] regulates InsP$_3$R channel gating by tuning the sensitivity of the channel to inhibition by high [Ca$^{2+}$], (Mak et al., 1998, 2001; Ionescu et al., 2006). Thus, in the presence of subsaturating [InsP$_3$] (33 nM), the Sf9 InsP$_3$R channel is inhibited at a relatively low [Ca$^{2+}$], so that $P_o$ at [InsP$_3$] = 33 nM and [Ca$^{2+}$] = 1 $\mu$M is lower than that at saturating [InsP$_3$] = 10 $\mu$M and [Ca$^{2+}$] = 1 $\mu$M (Fig. 3 A). This reduction in channel $P_o$ is mainly due to increases in $\langle \tau_i \rangle$ whereas $\langle \tau_o \rangle$ shows little dependence on [InsP$_3$] (Fig. 3 E). Modal analysis of InsP$_3$R channel current records obtained in [InsP$_3$] = 33 nM and [Ca$^{2+}$] = 1 $\mu$M revealed that the channels in subsaturating (33 nM) [InsP$_3$] exhibit the same three gating modes (H, I, and L modes) with very similar $P_o^M$ in each of the modes as

![Figure 2.](image-url) Distinct patterns of InsP$_3$R channel gating in each of the three modes as revealed by burst filtering. The current records were obtained in saturating 10 $\mu$M InsP$_3$ and [Ca$^{2+}$], as tabulated. Each record consists of a set of three traces of the same single channel current record: (top) unprocessed current trace, (middle) idealized current trace generated from current record using QuB software, and (bottom) idealized current trace after burst analysis. (A) InsP$_3$R gating in high-$P_o$, H, mode in which the channel opens mainly in bursts whose gating behavior is substantially affected by burst analysis. (B) InsP$_3$R gating in intermediate-$P_o$, I, mode with rapid opening and closing kinetics that is largely unaffected by burst analysis. (C) Channel gating in low-$P_o$, L, mode with brief openings separated by very long closed durations.
compared with channels in saturating (10 μM) [InsP₃]
(Fig. 3 B). Regulation of the overall channel $P_o$ by
[InsP₃] is therefore mediated by the effects of [InsP₃]
on $\pi^M$, which agrees with the observation that in subsat-
urating [InsP₃], the channel is inhibited by lower [Ca²⁺],
(Fig. 3 C). In 33 nM [InsP₃] and 1 μM [Ca²⁺], $\pi^M$ is not
very different from that for the channel in saturating
(10 μM) [InsP₃]. The ratio of $\pi^M$: $\pi$ in [Ca²⁺] = 1 μM
and [InsP₃] = 33 nM is smaller than that for a channel
in the same [Ca²⁺], but saturating 10 μM [InsP₃], as
inhibition by Ca²⁺ stabilizes the L mode relative to the H
mode. Since the gating kinetic properties ($\langle t_{o}^{M}\rangle$,$\langle t_{c}^{M}\rangle$, $\langle t_{b}^{M}\rangle$, and $\langle t_{g}^{M}\rangle$) of the channel in each mode are sig-
nificantly regulated by [Ca²⁺], and InsP₃ regulates
InsP₃R channel activity by altering the sensitivity of the
channel to Ca²⁺ regulation, these gating kinetic prop-
erties of the channel in each mode display dependence
on [InsP₃], as expected (Fig. 3, F–I).

**DISCUSSION**

We have here obtained long single-channel current rec-
ords with robust InsP₃R channel activities over a wide
range of [Ca²⁺] and [InsP₃] by patch clamp electrophys-
iology of isolated nuclei from SF9 cells. These records
have provided new insights into the gating behavior of
the InsP₃R channel. InsP₃R gating is modal, with three
distinct patterns of activity identified. Importantly, ligand
regulation of channel activity impinges directly upon this
modal gating behavior, with Ca²⁺ and InsP₃ regulating
the propensity of the channel to be in each of the three
estereotypic, relatively ligand-independent modes.
The InsP₃R Channel Gates in Three Modes

Based on an allosteric model that quantitatively accounted for single InsP₃R channel gating behaviors under a wide range of [InsP₃] and [Ca²⁺]ᵢ (Mak et al., 2003), a novel algorithm was developed to determine the gating mode of the InsP₃R with high temporal resolution and little ambiguity (Appendix and Figs. 4–6 therein). Our modal gating analysis determined that the InsP₃R channel gates with three different gating modes, each exhibiting distinct gating kinetics (Figs. 3 and 7 in Appendix). Although our algorithm is different from conventional modal analyses, which assign gating modes based on the average of some channel kinetic parameter (Blatz and Magleby, 1986; McManus and Magleby, 1988; Delcour and Tsien, 1993; Delcour et al., 1993; Catacuzzeno et al., 1999; Saftenku et al., 2001; Popescu and Auerbach, 2003; Popescu et al., 2004), its validity was confirmed by the clear separation of the values of channel Pₛ within the three gating modes in all [Ca²⁺]ᵢ examined (Fig. 3 C) despite the fact that channel Pₛ was not directly taken into consideration in the modal analysis algorithm.

Examination of the modal transitions identified by our modal analysis algorithm revealed that spontaneous transitions from any one of the modes into the other two occurred regularly despite the fact that the channels were exposed to constant levels of [InsP₃] and [Ca²⁺]ᵢ, during each experiment. Modal gating of ion channels cannot be accounted for by simple kinetic schemes that are linearly connected (Delcour and Tsien, 1993; Zahradnikova and Zahradnik, 1996). Rather, the observed interconnectivity between modes can only be accounted for by more complex, tiered kinetic schemes in which each mode has its own independent set (tier) of connected open and closed kinetic states, and the three tiers for the three modes are completely interconnected, as previously depicted (Delcour et al., 1993; Popescu and Auerbach, 2003; Popescu et al., 2004); or by kinetic schemes with a loop, as previously depicted (Zahradnikova and Zahradnik, 1996, 1999; Saftenku et al., 2001; Rosales et al., 2004). Thus, among the various kinetic models that have been proposed to account for InsP₃R-mediated Ca²⁺ signaling, the ones involving just a single explicit open channel kinetic state (for example see De Young and Keizer, 1992; Atri et al., 1993; Othmer and Tang, 1993; Bezprozvanny, 1994; Bezprozvanny and Ehrlich, 1994; Swillens et al., 1994; Dupont and Swillens, 1996; Marchant and Taylor, 1997; Hirose et al., 1998; Swillens et al., 1998; Adkins and Taylor, 1999; Swillens et al., 1999; Sneyd and Dufour, 2002; Watton and Taylor, 2002), cannot describe the modal gating behaviors observed in this study. Only kinetic models in which the InsP₃R channel has multiple independent open-to-closed transitions (Bruno et al., 2005) (for example see Kafstan et al., 1997; Moraru et al., 1999; Dawson et al., 2003; Mak et al., 2003; Fraiman and Dawson, 2004) have the potential to account for the observed modal gating behaviors. However, since all these models were developed to account for steady-state channel gating behavior under constant [InsP₃] and [Ca²⁺]ᵢ, they all need to be substantially expanded to describe the modal gating behaviors of the InsP₃R channel in which spontaneous transitions from one gating mode to another occurred regularly even in the presence of constant [InsP₃] and [Ca²⁺]ᵢ. As a starting point, we present in the Appendix (and Fig. 8 therein) the simplest model that quantitatively accounts for the InsP₃R channel modal gating behaviors observed.

Ligand Regulation of InsP₃R Channel Activity Is Mainly Mediated through Mode Switching

A surprising result of our modal analysis is that ligand regulation of InsP₃R channel activity (Pₛ), a critical aspect of regulation of InsP₃-mediated intracellular Ca²⁺ signaling, is mediated mainly by ligand regulation of the relative prevalence of the H mode vs. the L mode (Fig. 3 C). Within the range of [Ca²⁺]ᵢ and [InsP₃] examined, all the kinetics of the I mode (relative prevalence πᵢ, relative frequency ψᵢ, and mean dwell time (δᵢ) exhibit little [Ca²⁺]ᵢ or [InsP₃] dependencies (Fig. 3, C, D, and J). Mode switching is not the only mechanism for ligand regulation of InsP₃R channel kinetics, because detailed gating kinetics of the channel in individual modes (〈tᵢᵢ max〉 and 〈tᵢᵢ mean〉) are also significantly regulated by [InsP₃] and [Ca²⁺]ᵢ. We suggest that mode switching is nevertheless the most relevant mechanism of ligand regulation of InsP₃R-mediated Ca²⁺ release. InsP₃R channels are spatially localized in the ER in clusters (Mak and Foskett, 1994; Ionescu et al., 2006) with more than one active channel involved in the generation of various Ca²⁺ signaling events ranging from blips and puffs to propagating saltatory waves (Yao et al., 2007). Because the opening and closing kinetics of individual channels are averaged out over the multiple active channels involved, it is the Pₛ of the active InsP₃R channels that directly govern the amount of Ca²⁺ released and therefore the characteristics of the Ca²⁺ signal generated. Thus, ligand-dependent mode switching, which directly impinges on the channel Pₛ, is the major mechanism for ligand regulation of InsP₃R-mediated Ca²⁺ signals. Deeper understanding of the kinetic mechanisms responsible for modal gating behaviors of the channel will therefore provide further insights into ligand regulation of InsP₃R-mediated Ca²⁺ signaling.

Physiological Significance of InsP₃R Modal Gating

Modal gating kinetics have been observed in many different ion channels, including Cl⁻ channels (Blatz and Magleby, 1986; Catacuzzeno et al., 1999), “maxi” BK (Magleby and Pallotta, 1983a,b; McManus and Magleby,
1988; Rothberg et al., 1996), G protein–activated (Yakubovich et al., 2000) channels, NMDA (Popescu and Auerbach, 2003; Popescu et al., 2004) and nicotinic (Auerbach and Lingle, 1986; Naranjo and Brehm, 1993) receptors, N- (Delcour and Tsien, 1993; Delcour et al., 1993), P/Q- (Luvisetto et al., 2004), and L-type (Imredy and Yue, 1994) Ca$^{2+}$ channels, to name a few. Although different channel gating modes have been associated with distinct long-term channel kinetic features, including inactivation (Imredy and Yue, 1994), desensitization (Naranjo and Brehm, 1993), ligand inhibition (Delcour and Tsien, 1993), and quantitative features of subunit modulation (Luvisetto et al., 2004), the physiological significance of modal gating is in most cases not clear. Modal gating has also been observed in ryanodine receptors (RyRs), the other major intracellular Ca$^{2+}$ release channel with sequence homologies with InsP$_3$R, where it has been proposed to contribute to “adaptation” behavior of RyR in response to $[\text{Ca}^{2+}]_i$, jumps (Zahradnikova and Zahradnik, 1996; Zahradnikova et al., 1999; Fill et al., 2000; Rosales et al., 2004). However, the physiological significance of “adaptation” is also not clear, and the InsP$_3$R does not display similar “adaptation” behaviors in response to rapid changes in InsP$_3$ or Ca$^{2+}$ concentrations (Mak et al., 2007). The results here, by demonstrating that important ligand regulation of InsP$_3$R channel activity impinges primarily on modal gating, provide a clear demonstration of the physiological relevance of channel modal gating.

The modal gating analysis presented here was performed on single-channel current traces from insect S9 InsP$_3$R mainly because these channels remain active for long extensive periods during nuclear patch clamp experiments (mean channel activity duration $\sim$120 s; Ionescu et al., 2006). In retrospect, it appears that modal gating behavior was previously observed in nuclear patch-clamp records of diverse endogenous or recombinant channels from different InsP$_3$R isoforms (type 1 and 3) and splice variants (SII+/−) of different species (Xenopus laevis frogs and rat). Bursts of high channel activities (H mode) separated by long quiescent periods (L mode) were observed in endogenous Xenopus type 1 InsP$_3$R channels (Mak and Foskett, 1997; Mak et al., 1998). Single-channel current records of recombinant rat type 3 InsP$_3$R expressed in Xenopus oocytes presented by Mak et al. (2000, 2001) are reminiscent of the S9 InsP$_3$R channel current records exhibiting modal gating behaviors presented here (Fig. 2). Current records of recombinant rat type 1 InsP$_3$R channels expressed in mammalian COS-7 cells presented by Boehning et al. (2001) clearly exhibited the three gating modes. Furthermore, biphasic regulation of the relative prevalence of the H mode by Ca$^{2+}$ paralleling the biphasic Ca$^{2+}$ regulation of InsP$_3$R channel activity that is reported here was also clearly observable in the current records obtained in various $[\text{Ca}^{2+}]_i$, for different InsP$_3$R isoform channels from different species (Mak et al., 1998, 2001; Boehning et al., 2001). Thus, although a comprehensive study of modal gating behavior (like the one performed here for the S9 InsP$_3$R channels) was not feasible for the other InsP$_3$R channels because of their short channel activity durations due to channel rundown or inactivation (Mak and Foskett, 1997; Mak et al., 2000; Boehning et al., 2001), modal gating appears to have been widely observed in many different types of InsP$_3$R and probably plays a major role in ligand regulation of many if not all InsP$_3$R channels.

The important role modal gating plays in ligand regulation of InsP$_3$R activity indicates that besides the time scales of channel openings and closings ($t_\text{c}$ and $t_\text{c}$ $\sim$ ms, Fig. 3 E), other, longer time scales in InsP$_3$R channel gating kinetics are likely to be relevant for the kinetics of InsP$_3$-mediated intracellular Ca$^{2+}$ signaling in vivo. One such time scale is associated with the channel burst ($t_b$) and burst-terminating (interburst) gap ($t_g$) durations. Whereas most of the short channel closings are the result of ligand-independent channel gating (Mak et al., 2003; Foskett and Mak, 2004), the time scales of the bursts and gaps probably reflect the kinetics of ligand unbinding from and binding to, respectively, the channel and the associated InsP$_3$R conformational changes. This assumption is supported by the results of the modal gating analysis here (Appendix and Table II therein). Thus, the durations of the bursts and gaps, rather than the durations of channel opening and closing, probably provide a better measure of the kinetics of the response of the InsP$_3$R channel to ligand concentration changes.

A recent study of the kinetic responses of single InsP$_3$R channels to rapid ligand concentration changes observed that in the constant presence of saturating 10 $\mu$M InsP$_3$, the mean lag times to termination of InsP$_3$R channel activity from abrupt changes in $[\text{Ca}^{2+}]_i$, from optimal (2 $\mu$M) to subactivating (<10 nM) and/or inhibitory (300 $\mu$M) levels were 160 and 290 ms, respectively. In constant 2 $\mu$M Ca$^{2+}$, the mean lag time to channel activity termination from an abrupt drop in [InsP$_3$] from 10 $\mu$M to 0 was 700 ms (Mak et al., 2007). In those experiments, the channels were most likely in the H mode before the activity-terminating ligand concentration change, with mean burst duration $\left\langle t_b \right\rangle$ of 200–600 ms (Fig. 3 H). The similarity between the mean channel lag times observed in rapid perfusion experiments and the mean burst duration determined here suggests that the kinetics of channel responses to changes in ligand concentrations are likely determined by how fast the channel can exit from a burst when the ligand concentration change occurs. If that is the case, then instead of a channel opening, a channel burst probably constitutes a stereotypical single-channel InsP$_3$R Ca$^{2+}$-release event.

The weak dependence of channel burst duration on $[\text{Ca}^{2+}]_i$ may possibly be a mechanism by which an active
InsP₃R channel can avoid being prematurely inhibited by the Ca²⁺ that it releases, because an increase of [Ca²⁺], from 1 µM (optimal) to 89 µM (inhibitory) only reduces the burst duration from ~500 to ~300 ms when the channel is in H mode (Fig. 3 H). Moreover, the stabilization by activating [Ca²⁺], of the H mode (Fig. 3 J), which has significantly longer burst durations (Fig. 3 H), may possibly play an important role in Ca²⁺-induced Ca²⁺ release. Thus, in the presence of sufficiently high [InsP₃], an increase in [Ca²⁺], above the resting level can encourage an InsP₃R channel to enter the H mode from the L mode. As a result, the burst duration of the channel increases from that for an L mode (~10 ms), which may not release enough Ca²⁺ to recruit nearby channels to propagate a Ca²⁺ signal (individual blips or puffs) to that of an H mode (~200 ms), which enables the InsP₃R channel to continue releasing Ca²⁺ even when the local [Ca²⁺] is raised to a high level. Such long channel bursts can release sufficient Ca²⁺ to recruit neighboring InsP₃Rs or InsP₃R clusters for a regenerative Ca²⁺ signal (Berridge, 1997; Ionescu et al., 2006).

In summary, we have demonstrated that the InsP₃R gates with stereotypic behaviors in three distinct modes, and that mode switching accounts for most of the ligand regulation of InsP₃R Ca²⁺ release channel. Modal switching is therefore a novel major mechanism of physiological regulation of InsP₃R channel activity, with implications for the kinetics of Ca²⁺ release events in cells.

APPENDIX

New Algorithm Needed to Analyze Modal Gating Kinetics of InsP₃R Channels

Conventional modal gating analysis algorithms assign modes according to the value of a channel kinetic parameter, e.g., $P_o$, or channel opening or closing durations, averaged over current record segments either with a fixed duration (Delcour and Tsien, 1993; Delcour et al., 1993; Saftenku et al., 2001; Popescu and Auerbach, 2003; Popescu et al., 2004) or containing a fixed number of channel openings and closings (Blatz and Magleby, 1986; McManus and Magleby, 1988; Catacuzzeno et al., 1999). The InsP₃R channel exhibited closed channel durations that span several orders of magnitude (a few milliseconds to tens of seconds) in all ligand conditions examined (Fig. 1). Furthermore, the transitions between different gating patterns of the InsP₃R channel were abrupt (Fig. 1). Consequently, when short averaging segments were used in conventional algorithms, the value of the averaged parameter fluctuated wildly from segment to segment due to the small number of gating events present in each segment available for averaging, rendering separation of gating modes impossible. Conversely, using long averaging segments in conventional algorithms resulted in loss of temporal resolution and failure to capture the abrupt nature of the modal transitions. Thus, we developed a novel modal gating algorithm to determine the gating mode of the InsP₃R channel from its current record with high accuracy and high temporal resolution.

Burst Analysis of Idealized Single-Channel InsP₃R Channel Current Traces

Previous analyses of the gating kinetics of various InsP₃R channels have revealed that the regulation of channel $P_o$ by [Ca²⁺] and [InsP₃] is predominantly accounted for by ligand regulation of the mean channel closed duration ($t_c$) (Mak et al., 1998, 2001; Ionescu et al., 2006). In addition, the maximum channel $P_o$ is ~0.8, significantly <1, even under optimal ligand conditions, when the channel gates mainly with short openings (channel open duration $t_o$ ~10 ms) separated by very brief closings (channel closed duration $t_c$ ~1 ms). It was previously suggested that open InsP₃R channels can close either via ligand-independent or -dependent conformational transitions (Mak et al., 2003), with closures under optimal ligand conditions mediated predominantly via ligand-independent transitions. By visual inspection of current records of the Sf9 InsP₃R channel, we surmised that such ligand-independent transitions accounted for the majority of channel closings in one of the channel gating modes. To properly identify such a gating mode, we performed a burst analysis (Magleby and Pallotta, 1983a) to remove brief channel closings that probably originated from these ligand-independent transitions. Because the ligand-dependent channel closings occur more frequently under ligand conditions that engender low channel $P_o$, channel closed duration distributions under such conditions are more likely to reveal a clear segregation of the two populations of channel closings originating from ligand-dependent and -independent conformational transitions. The InsP₃R channel $t_c$ distribution (Fig. 4) for all current records obtained in [Ca²⁺] = 0.1 µM, when $P_o$ was low, suggested that 10 ms is a reasonable value for the minimum duration of a burst-terminating gap $T_{min}$ (Magleby and Pallotta, 1983a). Therefore, all channel closings with $t_c \leq T_{min} = 10$ ms were considered to be caused by ligand-independent channel conformational transitions, and were removed in our burst analysis as if they never occurred. Consequently, all channel closings have durations >10 ms after the burst analysis. Those channel openings that remained after burst analysis, presumably resulting from ligand-dependent transitions, are referred to as bursts with duration $t_o$, separated by burst-terminating gaps with duration $t_c > 10$ ms. Burst analysis with $T_{min} = 10$ ms was applied to all idealized single InsP₃R channel current records obtained in [Ca²⁺] = 0.1, 1, and 89 µM.

It should be noted that even when channel exhibited low $P_o$ in 10 µM InsP₃ and 0.1 µM Ca²⁺, the duration
The incomplete segregation of the short ligand-independent channel closings and the longer, ligand-dependent ones even in 0.1 μM Ca²⁺ and 10 μM InsP₃ when channel $P_o$ is low (Fig. 4) also means that because of the stochastic nature of channel gating, a fraction of the ligand-dependent channel closings have short durations. Consequently, they are indistinguishable from the ligand-independent ones and are removed by the burst filtering protocol and one (with $t_c > T_{gmin}$) retained. Under the circumstances, there is no “ideal” choice of the value of $T_{gmin}$. Any choice of $T_{gmin}$ will inevitably leave a population of closings with $t_c$ just $< T_{gmin}$, which, upon visual inspection, seem long enough to be retained, and a population of closings with $t_c$ just $> T_{gmin}$, which seem to be short enough to be filtered out. Our choice of $T_{gmin}$ as indicated in Fig. 4 minimized the number of such “ambiguous” closings for channels in 10 μM InsP₃ and 0.1 μM Ca²⁺.

The incomplete segregation of the short ligand-independent channel closings and the longer, ligand-dependent ones even in 0.1 μM Ca²⁺ and 10 μM InsP₃ when channel $P_o$ is low (Fig. 4) also means that because of the stochastic nature of channel gating, a fraction of the ligand-dependent channel closings have short durations. Consequently, they are indistinguishable from the ligand-independent ones and are removed by the burst filtering protocol and one (with $t_c > T_{gmin}$) retained. Our choice of $T_{gmin}$ as indicated in Fig. 4 minimized the number of such “ambiguous” closings for channels in 10 μM InsP₃ and 0.1 μM Ca²⁺.

Three Modes of InsP₃R Channel Gating
After burst analysis, three distinct patterns (modes) of InsP₃R channel gating were revealed in all [Ca²⁺]i. The channel gating kinetics in each mode were not significantly affected by the burst analysis. In the first mode, the channel has long bursts interrupted with gaps that are relatively brief (though $>10$ ms) so channel $P_o$ is high (Fig. 2, A and D). In the second mode, the InsP₃R channel gates frequently with mostly short openings and closings, so channel $P_o$ is moderate (Fig. 2, B and E). In the third mode, the channel has long closed periods interrupted with brief, infrequent openings, so channel $P_o$ is very low. Burst analysis does not significantly affect the kinetics of this mode (Fig. 2, C and F). Based on their kinetic characteristics, we refer to the three InsP₃R channel gating patterns as the high- (H), intermediate- (I), and low- (L) activity modes, respectively.

Detection of Modal Transitions and Gating Mode Assignment
To identify with high temporal resolution changes among the gating modes of the InsP₃R channel (modal transitions), durations of channel bursts and burst-terminating gaps ($t_b$ and $t_g$) in idealized, burst-analyzed single channel records were monitored. Either $t_b$ or $t_g$ crossing over some predefined abrupt thresholds $T_g$
640 Ligands Regulate InsP3R Channel through Mode Switching

and $T_b$, respectively, from above or below, could signify a modal transition. Visual examination of idealized current traces (both before and after burst analysis) together with plots of $t_g$ and $t_b$ for all single channel current records indicated that setting $T_b = 100$ ms and $T_g = 200$ ms allowed objective detection of channel modal transitions that correlated closely with observed changes in the patterns of channel gating kinetics (Fig. 5). Because a majority of burst-terminating gaps had $t_g \leq 200$ ms in all ligand conditions examined, a hysteresis requirement was implemented in the modal transition detection protocol to avoid overfragmenting the channel gating modes. Thus, a modal transition was recognized only when two or more consecutive burst-terminating gaps had $t_g \leq 200$ ms following one or several consecutive gaps with $t_g > 200$ ms (blue arrowheads in Fig. 5 B). Similarly, a majority of channel bursts had $t_b \leq 100$ ms in all ligand conditions examined. Therefore, whereas a modal transition was registered when a single channel burst had $t_b > 100$ ms following a series of bursts with $t_b \leq 100$ ms, a modal transition was only registered when two consecutive channel bursts had $t_b \leq 100$ ms following a series of bursts with $t_b > 100$ ms.

After the modal transitions were identified, the channel was then classified as being in the I mode if $t_g \leq T_g$ and $t_b \leq T_b$; in the H mode if $t_g \leq T_g$ and $t_b > T_b$; and in the L mode if $t_g > T_g$ and $t_b \leq T_b$ (Fig. 6). Cases in which a burst-terminating gap with $t_g > T_g$ occurred adjacent to a burst with $t_b > T_b$ were rare and considered to be modal transitions between L and H modes occurring between the burst and the gap (Fig. 6).

Channel mode assignments in this algorithm are based on the durations of two consecutive pairs of channel bursts and gaps rather than on the values of channel parameters ($t_o$, $t_c$, or $P_o$) averaged over some window.

Figure 5. Identification of InsP3R channel gating modes based on channel opening and closing durations. The single InsP3R channel current records were obtained in saturating 10 μM InsP3, and optimal (1 μM) and nonoptimal (89 μM) [Ca2+] as tabulated. Each section consists of a set of five graphs derived from the same channel record. From the top: idealized current trace, idealized current trace after burst analysis, plot of channel burst duration $t_b$ vs. time when the channel opens, plot of channel gap duration $t_g$ vs. time when the channel closes, and the gating mode of the channel, determined as described in the text, with green, yellow, and red representing H, I, and L modes, respectively. The current traces were selected to show modal transitions among all three gating modes in one continuous recording under various [Ca2+].
Figure 6. Scheme to determine channel gating mode based on the durations of adjacent channel bursts and burst-terminating gaps. The gating mode of the channel is assigned as indicated in a graph of channel burst duration $t_b$ vs. duration of the adjacent burst-terminating gap $t_g$ as shown. When a channel gap with $t_g > T_g$ occurred next to a channel burst with $t_b > T_b$ (area with yellow and green hatching), the channel is considered to undergo a modal transition from L to H mode (if the channel gap preceded the burst) or from H to L mode (if the burst preceded the gap).

(containing a constant number of openings and closings or lasting a constant time). Thus the assignment has high temporal resolution. Implementation of the hysteresis requirement improves the accuracy of the mode assignment by the algorithm.

Because mode assignment is based directly on only the durations of channel bursts ($t_b$) and burst-terminating gaps ($t_g$), there is no intrinsic restriction that the channel $P_o$ within each gating mode should remain consistent among various ligand conditions. In fact, the values of the thresholds $T_g$ and $T_b$ used in the modal analysis only limit the value of channel $P_o$ in the modes to: $0 \leq P_o^H \leq 0.33$; $0 \leq P_o^M \leq 1$; and $0.33 \leq P_o^L \leq 1$. Therefore, the consistency of the values of $P_o^M$ for the three gating modes observed for various ligand conditions validates the identification of the three modes using the modal analysis algorithm.

Evaluation of InsP$_3$R Channel Gating Kinetic Parameters
Overall and in Individual Gating Modes
Segment(s) of single-channel InsP$_3$R channel current records with stable baseline current levels were selected from each of the many experiments performed under various ligand concentration conditions (Table I). Segments shorter than 5 s were not used for modal analysis because their lengths are comparable to the mean modal dwell times $\langle \tau^M \rangle$, which causes an artificial bias against long modal durations. Nevertheless, durations of selected segments from one experiment (showing the gating activity of one single InsP$_3$R channel) varied greatly, from 5 s to $>750$ s, depending on the stability of the giga-ohm seal between the patch-clamp micro-pipette and the isolated membrane patch, and the duration of activity of the InsP$_3$R channel before inactivation or rundown. To provide proper weighing for experiments of different durations, the kinetic parameters for InsP$_3$R channel gating were evaluated using event-based statistics. This means that each opening (or closing) event from any experiment performed with the same set of ligand conditions was considered equivalent. Thus the mean open (or closed) duration $\langle t \rangle$ is given by

$$\langle t \rangle = \left\{ \sum_{j=1}^{M} \frac{N_j}{\sum_{j=1}^{M} N_j} \right\}^{-1} \sum_{j=1}^{M} \sum_{i=1}^{N_j} t_{ij},$$

(A1)

where $t_{ij}$ is the duration of the $j^{th}$ of $N_j$ opening (or closing) events in the $i^{th}$ of $M$ experiments performed in the set of ligand conditions in question (Fig. 3 E). Channel $P_o$ (Fig. 3 A) is evaluated as the ratio of the sum of all open durations to the sum of all durations (open or closed). Similarly, the mean open (closed, burst, or gap) duration for each gating mode was evaluated by averaging with equal weight the durations of all the openings (closings, bursts, or gaps) in all the periods when the channel was determined to be in that mode by the modal analysis algorithm, regardless of which experiment the event was recorded in as long as the experiment was performed under the same set of ligand conditions (Fig. 3, F–I). Channel $P_o^M$ was evaluated as the ratio of the sum of all open durations to the sum of all durations (open or closed) in a particular mode (Fig. 3 B). The mean modal dwell times $\langle \tau^M \rangle$ (Fig. 3 J) were evaluated using Eq. A1 with all dwell times of the mode from any experiment (using the same ligand conditions) weighted equally.

The duration distributions for channel openings and closings in general, and the distributions within each gating mode for channel openings, closings, bursts, and gaps, were all determined to be non-Gaussian by the Jarque-Bera (Jarque and Bera, 1987) and Kolmogorov-Smirnov (Khamis, 2000) tests. Thus, nonparametric statistical analyses were used to characterize and compare the distributions. The ranges of the distributions were described in terms of the standard deviations evaluated by the random bootstrap resampling method (Efron and Tibshirani, 1993; Mooney and Duval, 1993), and statistical significance of the differences between the durations was evaluated using the two-tailed nonparametric Wilcoxon-Mann-Whitney rank-sum test (Cheung and Klotz, 1997).

Because of the large numbers of events available from extensive experimental current records for each set of ligand conditions, the standard deviations of the durations $t_b$, $t_g$, $t_c$, $t_o^M$, $t_c^M$, $t_o^L$, and $t_g^M$ are too small to be plotted in Fig. 3 (the error bars are all smaller than the symbols in the graphs). The errors in the values of channel $P_o$ and $P_o^M$, derived from the durations, are also too small to be plotted. According to the nonparametric Wilcoxon-Mann-Whitney rank-sum test, most kinetic...
quantities obtained under optimal (1 μM) Ca\(^{2+}\) and saturating (10 μM) InsP\(_3\) were significantly different when compared with corresponding quantities obtained under other ligand conditions, low (100 nM) Ca\(^{2+}\) and saturating InsP\(_3\), inhibitory (89 μM) Ca\(^{2+}\) and saturating InsP\(_3\), optimal Ca\(^{2+}\) and subsaturating (33 nM) InsP\(_3\).

Whereas event-based statistics may provide more accurate estimation of the channel gating parameters by taking into consideration the very different lengths of channel activity recorded in various experiments, the calculation gives no estimate of the experiment-to-experiment variability of the kinetic parameters. To gauge the reproducibility of the experiments, the kinetic parameters (\(\langle t_0 \rangle\), \(\langle t_c \rangle\), \(\langle t_{mo} \rangle\), \(\langle t_{mc} \rangle\), \(\langle t_{mb} \rangle\), \(\langle t_{mg} \rangle\), \(\langle \tau_{M} \rangle\)) were also evaluated by experiment-based statistics, so that

\[
\langle t \rangle = \frac{1}{M} \left[ \sum_{j=1}^{M} \left( \frac{1}{N_j} \sum_{i=1}^{N_j} t_{ij} \right) \right] = \frac{1}{M} \left[ \sum_{j=1}^{M} \langle t \rangle_j \right],
\]

where symbols are similar to those used in Eq. A1. As shown in the second half of Eq. A2, the average durations are evaluated as the mean of the mean durations from individual experiments. The channel open probabilities (\(P_o\) and \(P_{mo}\)) derived by experiment-based statistics are similarly evaluated as the mean of channel open probabilities from individual experiments. More importantly, the standard deviations of these quantities derived by random bootstrap resampling provide some measure of the reproducibility of the experiments. The kinetic parameters and their standard deviations derived through experiment-based statistics are plotted in Fig. 7.

Despite the larger standard deviations of the kinetic quantities evaluated by experiment-based statistics, a comparison, using Wilcoxon-Mann-Whitney rank-sum test, of kinetic quantities obtained under optimal [Ca\(^{2+}\)] (1 μM) and saturated [InsP\(_3\)] (10 μM) and saturating InsP\(_3\) with those obtained in other ligand conditions revealed statistically significantly difference in a majority of the quantities.

Validation of Modal Gating Analysis Algorithm

The algorithm developed to analyze channel modal gating kinetics used three parameters: the minimum

Figure 7. InsP\(_3\)R channel gating parameters in various [Ca\(^{2+}\)], and [InsP\(_3\)] evaluated using experiment-based statistics (see Appendix). The same channel gating parameters are plotted in the same panels with the same symbols and color code as in Fig. 3: (A) channel open probability \(P_o\); (B) channel open probability in each of the three gating modes \(P_{mo}\); (C) relative prevalence \(\pi^M\) for the three gating modes; (D) relative frequency \(f^M\) of the gating modes; (E) mean overall channel opening \(\langle t_0 \rangle\) and closing \(\langle t_c \rangle\) duration; (F–I) mean durations of channel opening \(\langle t_{mo} \rangle\), closing \(\langle t_{mc} \rangle\), bursts \(\langle t_{mb} \rangle\), and burst-terminating gaps \(\langle t_{mg} \rangle\), respectively, for the gating modes; (J) mean duration \(\langle \tau_{M} \rangle\) of the gating modes. Error bars in (A, B, and E–J) indicate standard errors of the mean evaluated using experiment-based statistics (see Appendix). Parameters marked with asterisks are those observed in suboptimal ligand concentrations that are statistically significantly different from those observed in optimal [Ca\(^{2+}\)] (1 μM) and saturated [InsP\(_3\)] (10 μM).
The virtual current records were analyzed using our modal analysis algorithm. The error rate of the algorithm was estimated by comparing the results of the analysis with the known kinetic states of the channel from the simulation. The error rate of the algorithm was approximately 3.5% for all [Ca²⁺] examined (0.1, 1, and 89 μM). The error rate approximately doubled for every threefold increase in the modal transition rates (H→I, H→L, and L→H rates) used in the simulation. Thus, although there must be some inherent inaccuracies in modal transition rates used in the simulation because they were based on the modal properties derived by the modal analysis algorithm, the effects of such inaccuracies on the error rates are not significant. Finally, only 3% of a virtual current record generated for a channel in the H mode only (H→I and H→L rates = 0) and <1% of virtual current records generated for channels only in the I or L modes were misidentified. Thus, our modal analysis protocol identifies the kinetic modes of an InsP₃R channel from its current record with high accuracy and high temporal resolution.
