Running title: p70S6K signaling to the actin cytoskeleton

Keywords: p70 S6 kinase; ovarian cancer; actin; Rac1; Cdc42

The authors declare no conflict of interest.

Word count: 4418
Abstract

Ovarian cancer is highly metastatic with a poor prognosis. The serine/threonine kinase, p70 S6 kinase (p70S6K), which is a downstream effector of phosphatidylinositol 3-kinase/Akt pathway, is frequently activated in ovarian cancer. Here, we show that p70S6K is a critical regulator of the actin cytoskeleton in the acquisition of the metastatic phenotype. This regulation is through two important activities: p70S6K acts as an actin filament cross-linking protein and as a Rho family GTPase-activating protein. Ectopic expression of constitutively active p70S6K in ovarian cancer cells induced a marked reorganization of the actin cytoskeleton and promoted directional cell migration. Using cosedimentation and differential sedimentation assays, p70S6K was found to directly bind to and cross-link actin filaments. Immunofluorescence studies showed p70S6K colocalized with cytochalasin D-sensitive actin at the leading edge of motile cells. p70S6K did not affect the kinetics of spontaneous actin polymerization, but could stabilize actin filaments by the inhibition of cofilin-induced actin depolymerization. In addition, we showed that p70S6K stimulated the rapid activation of both Rac1 and Cdc42, and their downstream effector p21-activated kinase (PAK1), but not RhoA. Depletion of p70S6K expression or inhibition of its activity resulted in significant inhibition of actin cytoskeleton reorganization and reduced migration, with a concomitant reduction in Rac1, Cdc42, and
PAK1 activation, confirming that the effect was p70<sup>S6K</sup> specific. Similarly, the actin cytoskeleton reorganization/migratory phenotype could be reversed by expression of dominant negative Rac1 and Cdc42, or inhibition of PAK1. These results reveal a new direction for understanding the oncogenic roles of p70<sup>S6K</sup> in tumor progression.
Introduction

Ovarian cancer is the leading cause of death among all gynecological malignancies (Jemal et al., 2009). Nearly 70% of patients are diagnosed at the advanced stages, which have already metastasized cancer cells that detach from the primary tumor, spread throughout the peritoneum forming malignant ascites, adhere to and eventually invade organs within the peritoneal cavity. No effective therapy for advanced or metastatic ovarian carcinoma is currently available, and the poor 5-year survival rate is <25%. Thus, it is important to better understand the mechanisms by which these cells acquire metastatic properties and to identify new potential molecular targets.

p70 S6 kinase (p70\textsuperscript{S6K}) is a downstream effector of the phosphatidylinositol 3-kinase (PI3K)/Akt pathway, which is frequently activated in human ovarian cancer (Shayesteh et al., 1999; Philp et al., 2001; Altomare et al., 2004). p70\textsuperscript{S6K} is also well known to be activated by cytokines and growth factors, including epidermal growth factor and hepatocyte growth factor (HGF), which are potent inducers of p70\textsuperscript{S6K} in ovarian cancer (Liu et al., 2006; Zhou and Wong, 2006). Constitutive activation of p70\textsuperscript{S6K} is significantly more prevalent in malignant ovarian tumors than in benign lesions (Castellvi et al., 2006). Recently, in addition to its well-established role in regulating proliferation and cell
survival, we show for the first time that p70^{S6K} may be involved in other aspects of ovarian cancer progression, such as metastasis (Wong et al., 2004; Zhou and Wong, 2006; Pon et al., 2008). However, the role of p70^{S6K} in cell migration, which is a key process directly linked to cancer invasion and metastasis, has not been established, and the mechanism by which p70^{S6K} contributes to this process is also unknown.

Reorganization of the actin cytoskeleton is both essential and central for cell migration (Pantaloni et al., 2001). Motile cancer cells must assemble and disassemble the actin filaments at their leading edges as they move forward. Thus, deregulation of the expression or properties of actin-binding proteins that regulate the polymerization/depolymerization of actin into filaments, and cross-linking of these into bundles could influence metastasis (Pawlak and Helfman, 2001). The Rho family of small GTPases, in particular Rac1, Cdc42, and RhoA, are molecular switches that control the organization and dynamics of the actin cytoskeleton (Ridley et al., 2003; Raftopoulou and Hall, 2004): Rac1 regulates the formation of membrane ruffles (lamellipodia), Cdc42 triggers membrane projections (filopodia), and RhoA regulates stress fiber and focal adhesions. In addition, Rac1 is essential for forward cellular movement and Cdc42 is required for dictating the direction of migration.
In the present study, we show for the first time a role for p70^S6K in the directed migration of human ovarian cancer cells. We also provide mechanistic insights suggesting that this tumorigenic activity is associated with the ability of p70^S6K to directly and indirectly reorganize the actin cytoskeleton through its actin filament cross-linking and Rac1/Cdc42-activating activities.

Results

*p70^S6K* activation causes reorganization of the actin cytoskeleton

The rapid reorganization of the actin cytoskeleton is a critical early event in cell migration (Pantaloni *et al.*, 2001). To address if p70^S6K modifies actin organization in the cell, we tested the effects of constitutively active p70^S6K activation on the actin cytoskeleton in CaOV-3 and SKOV-3 ovarian cancer cell lines, which represent advanced human ovarian cancer (Buick *et al.*, 1985). When constitutively active p70^S6K (∆N_{54}∆C_{104} and D_{3}E-E_{398}) was ectopically expressed, there was a marked difference in both cellular morphology and actin cytoskeleton architecture. ∆N_{54}∆C_{104} - and D_{3}E-E_{398}-transfected cells had prominent actin-rich projections in the form of lamellipodia, actin microspikes, and filopodia which were absent in the untransfected cells (Figure 1a). Even after 24 h, there were no protrusions present in the control cells (data not shown).
To further demonstrate the effect of p70\textsuperscript{S6K} in altering the actin cytoskeleton, we utilized a siRNA specifically engineered towards p70\textsuperscript{S6K}. In these studies, HGF was used to activate endogenous p70\textsuperscript{S6K}, because HGF is highly expressed in ovarian cancer ascites inducing migration of cultured ovarian cancer cells (Sowter \textit{et al.}, 1999). Overexpression of the HGF receptor Met is associated with ovarian cancer progression and high Met expression correlates with poor survival (Sawada \textit{et al.}, 2007). The p70\textsuperscript{S6K}-specific siRNA, but not the nonspecific siRNA, was effective in depleting p70\textsuperscript{S6K} expression as confirmed by Western blotting (Figure 1b, inset). We observed that p70\textsuperscript{S6K} siRNA treated ovarian cancer cells resulted in dramatically reduced HGF-stimulated actin reorganization and reduced formation of membrane protrusions (Figure 1b). A second p70\textsuperscript{S6K} specific siRNA was also used, and comparable results were obtained, which confirms that p70\textsuperscript{S6K} was responsible for this effect (data not shown). In contrast, nonspecific siRNA did not obviously alter the pattern of actin distribution. Similar results were observed in cells treated with rapamycin, which is a small molecule inhibitor of p70\textsuperscript{S6K} kinase activity (Figure 1b). Together, these data show that p70\textsuperscript{S6K} activation plays a critical role in the reorganization of actin cytoskeleton.
\textit{p70^{S6K} is required for directional migration}

Because directed cell migration is a prerequisite of metastasis, we assessed the role of p70^{S6K} on cell migration using scrape wounding assays combined with Golgi tracking (Ridley \textit{et al.}, 2003). We found that p70^{S6K} siRNA treated cells migrated less efficiently than the control nonspecific siRNA treated cells, and also exhibited significantly reduced directional persistence (98\% inhibition of a polarized orientation of the Golgi apparatus) in the presence of HGF (Figure 2a). The role of p70^{S6K} in directional cell migration was further evaluated by measuring the movement of the cells towards a chemotactic stimulus using Boyden chamber assays. Activation of p70^{S6K} significantly promoted a motile phenotype, as detected by a 2.8-fold increase in cell motility compared with control cells (Figure 2b). In contrast, the HGF-enhanced migration was effectively suppressed by siRNA-mediated depletion of p70^{S6K} to near basal levels (Figure 2b). Under these conditions, and consistent with previous observation (Corps \textit{et al.}, 1997), HGF did not cause significant alterations of cell proliferation (Supplementary Figure 1). We also found no effect of constitutively active p70^{S6K} on cell proliferation (Supplementary Figure 1), indicating that the increase in cell migration was not because of a proliferative effect.
p70^{S6K} binds directly to actin

To begin to understand the mechanism of p70^{S6K} involvement in signaling the actin cytoskeleton, we used a cosedimentation assay to investigate if p70^{S6K} binds actin filament in vitro. As shown in Figure 3a, endogenous active p70^{S6K} readily cosedimented with actin. Moreover, stimulation of HGF increased the amount of phospho-p70^{S6K} sedimented in the actin pellet, suggesting that activated p70^{S6K} can more capably associate with actin.

We further asked whether the interaction of p70^{S6K} with actin by direct interaction or is mediated by other actin-binding proteins. To test this, an in vitro actin binding assay was performed using highly purified active p70^{S6K}. Figure 3b shows that the purified p70^{S6K} could be readily coprecipitated with actin in a concentration-dependent manner. p70^{S6K} alone did not pellet, indicating that the pelleting is due to binding to F-actin (Figure 3c). The fact that no other proteins were involved indicates a direct association between p70^{S6K} and actin.

This interaction was additionally verified by colocalization analysis using immunofluorescence microscopy. While phospho-p70^{S6K} was located diffusely through the control cells, it was translocated to and, interestingly, concentrated in lamellipodia, actin microspikes, and filopodia where it was extensively colocalized with actin upon
stimulation with HGF (Figure 3d, left). We further confirmed our results using myc-tagged D$_3$E-E$_{398}$. We found that D$_3$E-E$_{398}$ was colocalized with actin at membrane protrusions of lamellipodia and filopodia (Figure 3d, right). These changes were inhibited by disruption of actin filaments by cytochalasin D treatment (Figure 3e), indicating that the binding of p70$^{S6K}$ to the cytoskeleton is mediated by actin. Similar experiments with SKOV-3 revealed p70$^{S6K}$-actin interaction indistinguishable from those in CaOV-3 (Supplementary Figures 2a and b).

**p70$^{S6K}$ cross-links and stabilizes F-actin**

To further establish the role that p70$^{S6K}$ plays in the actin cytoskeleton, we repeated the cosedimentation assay, this time using a low-speed (14,000 g) to pellet the bundled or cross-linked actin filaments, while the free actin filaments remain in the supernatant. HGF caused the majority of actin filaments to pellet with endogenous phospho-p70$^{S6K}$ during low speed centrifugation, suggesting that active p70$^{S6K}$ is cross-linking individual filaments into actin bundles (Figure 4a and Supplementary Figure 2c). This was also examined using purified proteins: F-actin was detected in the supernatant when p70$^{S6K}$ was absent, but in the pellet when p70$^{S6K}$ was present, with an increasing shift between free to bundled actin with increasing molar concentrations of p70$^{S6K}$ (Figure 4b). Light
scattering assay was used to monitor the kinetics of p70S6K-induced actin bundle formation. Light scattering increased rapidly and reached almost steady state within 5 min, indicating that p70S6K quickly binds to actin filaments. Light scattering also increased with increasing concentrations of p70S6K, suggesting that more actin bundles were formed (Figure 4c). We also used electron microscopy to visualize the F-actin bundling. In the absence of p70S6K, actin filaments formed a uniform meshwork of fine filaments but did not show bundling. In contrast, robust multifilament bundles were clearly seen (Figure 4d). These closely apposed bundles were often slightly curved, suggesting flexible cross-linking.

The possibility of a physical interaction between p70S6K and actin suggests that p70S6K may affect the kinetics of actin polymerization. p70S6K did not change the rate or the extent of polymerization, suggesting that unlike other common activities of these proteins, actin polymerization is not a generic property of p70S6K (Figure 5a). On the other hand, p70S6K significantly decreased the rate and extent of actin filament depolymerization (Figure 5b). Fluorescence from pyrene-labeled F-actin decreased rapidly after addition of cofilin. This decrease in fluorescence was largely reduced with F-actin pre-incubated with purified p70S6K, suggesting p70S6K prevented depolymerization of F-actin induced by cofilin. These results indicate that in addition to
cross-linking of F-actin, p70\textsuperscript{S6K} also stabilizes filaments.

\textit{p70\textsuperscript{S6K} induces activation of Rac1 and Cdc42}

We next sought to determine the molecular mechanism by which p70\textsuperscript{S6K} regulates actin organization. Three members of the Rho family GTPases, Rac1, Cdc42, and RhoA, are best known for their effects on the actin cytoskeleton (Hall, 1998). In fibroblasts, it has been shown that Rho GTPases have the potential to regulate p70\textsuperscript{S6K}, suggesting that p70\textsuperscript{S6K} may be a downstream effector (Berven \textit{et al.}, 2004; Chou and Blenis, 1996). However, transfection with dominant negative Rac (N17Rac1), Cdc42 (N17Cdc42), or Rho (N19RhoA) failed to block p70\textsuperscript{S6K} phosphorylation (activation) upon HGF stimulation in CaOV-3 cells (Supplementary Figure 3a). Similarly, ectopic expression of constitutively active Rac (L61Rac1), Cdc42 (V12Cdc42), and Rho (V14RhoA) were unable to activate p70\textsuperscript{S6K} (Supplementary Figure 3b).

Because its roles in actin cytoskeleton reorganization similar to the activation of Rho GTPases, we investigated if p70\textsuperscript{S6K} might act upstream of Rho GTPases. To explore this possibility, we tested the effects of p70\textsuperscript{S6K} on Rac1, Cdc42, and RhoA activation using a pull-down assay that specifically recognizes the active GTP-bound form. As shown in Figure 6a, HGF rapidly increased activities of Rac1 and Cdc42 within 15-30 min, and
Rac1 and Cdc42 activation also coincided with the activation of p70S6K. In addition, expression of active p70S6K potently stimulated the activation of both Rac1 and Cdc42, whereas it did not have an effect on RhoA (Figure 6a), which is consistent with its enrichment in lamellipodia and filopodia (Fig. 1). To further elucidate the activation of Rac1 and Cdc42 was p70S6K specific, we used siRNA. In cells transfected with p70S6K siRNA, but not control siRNA, the ability of HGF to activate Rac1 and Cdc42 was abrogated (90% inhibition) (Figure 6b). Similarly, HGF-dependent activation of Rac1 and Cdc42 was also blocked in the presence of rapamycin (80% inhibition) (Figure 6c). Similar results were obtained with SKOV-3 cells (Supplementary Figures 2d and e). These results identify p70S6K as an upstream regulator of Rac1 and Cdc42.

*Rac1 and Cdc42 are mediators of p70S6K-regulated actin reorganization*

To investigate if p70S6K signals the actin cytoskeleton via Rac1 and Cdc42, we examined the actin cytoskeleton of cells cotransfected with myc-tagged dominant negative mutants of Rac1 and Cdc42 and GFP-tagged constitutively active p70S6K. Expression of N17Rac1 or N17Cdc42 was shown to clearly inhibit the p70S6K-induced restructuring of the actin cytoskeleton (Figure 7a). Conversely, constitutively active Rac1 and Cdc42 enhanced cell spreading and caused reorganization of the actin cytoskeleton (lamellipodia/filopodia) to...
levels similar to those observed in p70S6K-expressing cells (Figure 7b). To explore the relationship between p70S6K and Rac1/Cdc42, we investigated a possible interaction between these two proteins. Figure 7c demonstrates a colocalization of phospho-p70S6K with Rac1/Cdc42 in HGF-stimulated cells, but not in control cells.

The p21-activated kinase (PAK1) is a well-characterized effector of both Rac1 and Cdc42 and is essential for regulating leading edge actin dynamics (Dummler et al., 2009). Our finding that the activities of both Rac1 and Cdc42 are important in p70S6K-mediated actin cytoskeleton reorganization prompted us to assess the role of PAK. We found that p70S6K was able to stimulate the phosphorylation of PAK1, and that stimulation was lost in HGF-treated cells transfected with the p70S6K siRNA (Figure 8a). Knocking down PAK1 impaired the pronounced lamellipodia/filopodia phenotype in response to transfection of constitutively active p70S6K (Figure 8b). These cells also displayed a loss of the motile phenotype (Figure 8c). Another PAK1 siRNA also showed comparable results (Figure 8), whereas a nonspecific siRNA had no effect. These data demonstrate an essential role of Rac1/Cdc42/PAK1 signaling in actin cytoskeleton reorganization and the regulation of ovarian cancer cell motility downstream of p70S6K.
Discussion

In this study, we have successfully identified p70\textsuperscript{S6K} as a novel regulator of the actin cytoskeleton and found that it is pivotal for the directed migration of ovarian cancer cells. We show that two important properties underlie this function of p70\textsuperscript{S6K}, namely actin cross-linking and Rac1 and Cdc42 activation (Figure 9). Several aspects of this function are worth highlighting. We showed for the first time that p70\textsuperscript{S6K} was able to bind to F-actin with no other proteins involved, indicating direct binding of p70\textsuperscript{S6K} to F-actin. The finding that p70\textsuperscript{S6K} F-actin structures were cytochalasin D sensitive emphasizes the possibility that \textit{in vitro} interactions of p70\textsuperscript{S6K} with F-actin may represent direct interactions of p70\textsuperscript{S6K} with actin filaments \textit{in vivo}. Moreover, the binding of p70\textsuperscript{S6K} to F-actin was more potent in the presence of phosphorylation than in its absence, suggesting a dynamic regulation of p70\textsuperscript{S6K} association with the cytoskeleton and reinforces the notion that actin reorganization and cell migration are finely tuned events. This also implies that the actin-binding domain in p70\textsuperscript{S6K} may normally be hidden when this protein is in an inactive conformation.

An intriguing aspect concerns the biological function of such an interaction. The finding that p70\textsuperscript{S6K} both cross-links and stabilizes actin filaments suggests a role for p70\textsuperscript{S6K} in
regulating actin dynamics. Several key actin-binding proteins such as α-actinin, fimbrin, and fascin also function to regulate actin bundling (Holmes et al., 1976; Hanein et al., 1997). Because p70S6K has a well-established role in protein synthesis, this interaction may also have significance in synthesizing local proteins important for propagating the migratory response. For example, β-actin mRNA has been shown to localize to the leading lamella and its active translation there is important for cell migration (Kislauskis et al., 1994; Latham et al., 1994).

The Rho family of GTPases are critical regulators of actin reorganization. Studies using fibroblasts have suggested that Rho GTPases and p70S6K may reside on a common signaling pathway, and indeed these studies indicate that Rho GTPases are upstream activators of p70S6K (Chou and Blenis, 1996; Berven et al., 2004). In contrast to the above data, we found that, in ovarian cancer cells, Rac1 and Cdc42 did not regulate p70S6K function. Rather, Rac1 and Cdc42 are downstream effectors of p70S6K. One possible explanation is that this action may be cell-type dependent. Clearly, epithelial cells and fibroblasts display distinct architecture of the actin cytoskeleton. Rac has been demonstrated to evoke different responses depending on the cell type (Takaishi et al., 1997; Sander et al., 1998). Another possibility, and one that is supported by the findings
reported here, is that it may be related to the different functions of p70\textsuperscript{S6K}. It is interesting to note that activation of p70\textsuperscript{S6K} by Rac1 and Cdc42 appears to be independent of the ability of these Rho GTPases to regulate the cytoskeleton (Chou and Blenis, 1996). In contrast, we show that Rac and Cdc42 mediate signaling from p70\textsuperscript{S6K} is related to cytoskeletal reorganization, which Rac/Cdc42 are known to function during this process (Hall, 1998).

The increase in Rac1 and Cdc42 activities in response to p70\textsuperscript{S6K} sheds new light on the biochemical mechanism of p70\textsuperscript{S6K} function and identifies p70\textsuperscript{S6K} as a novel, important regulator of Rho GTPases. How does p70\textsuperscript{S6K} control the function of Rac1/Cdc42? Guanine nucleotide exchange factors (GEFs) are known to activate Rho GTPases by regulating the exchange of GDP for GTP. The Dbl homology-Pleckstrin homology (DH-PH) motif, present in many of proteins such as GEFs, is responsible for activation of Rac1 and Cdc42 (Erickson and Cerione, 2004). However, p70\textsuperscript{S6K} does not contain a DH-PH domain or other motifs that may elicit GEF activity. Given the fact that TOR proteins regulate Rho GTPase activity via a GTP exchange factor, ROM2, in yeast (Schmidt et al., 1997), it is possible that an additional protein, such as GEF, may be necessary for p70\textsuperscript{S6K}-mediated Rac1/Cdc42 activation. We also showed an essential role
for PAK1 in Rac1/Cdc42-mediated actin cytoskeleton reorganization downstream of p70^S6K. This finding is intriguing because PAK1 has been observed as the predominant isoform that is frequently activated in ovarian tumors and appears to be associated with tumor aggressiveness (Schraml et al., 2003; Siu et al., 2009). Once activated, PAK1 may locally affect the actin organization via direct phosphorylation of key signaling targets. For example, PAK1 phosphorylates and inactivates the actin-depolymerizing protein coflin leading to actin filament stabilization (Dummler et al., 2009). The observation that p70^S6K can also physically cross-link and stabilize the filaments suggests that multiple mechanisms that control stable actin structures are likely to be regulated by p70^S6K and gives support that this kinase is a critical regulator of the actin cytoskeleton.

The ability of p70^S6K to modulate dynamics of the actin cytoskeleton suggests that many oncogenic pathways could govern tumor invasion/metastasis by modulating p70^S6K. p70^S6K activation did not cause significant alteration to the actin cytoskeleton of normal OSE (Supplementary Figure 4), which suggests that the effect may be specific to ovarian cancer cells. It also complements our previous finding and other studies that showed a differential effect on OSE (Wong et al., 2004; Theriault et al., 2007) and the acquisition of a motile, fibroblast-like phenotype in OSE may be regulated independent of PI3K and
is a slow process (Ahmed et al., 2006). We and others have described the frequent activation of p70S6K in ovarian cancer cells than in normal OSE, suggesting a critical role for p70S6K in ovarian cancer development and progression (Wong et al., 2004; Castellvi et al., 2006; Pon et al., 2008). The observation that p70S6K was highly expressed and activated in high-grade, poorly differentiated ovarian carcinomas further suggests that p70S6K may be associated with tumor aggressiveness. Possible involvement of p70S6K in the regulation of cell migration is also particularly intriguing because the malignant phenotypes from patients with advanced breast cancer, colon cancer, and hepatocellular carcinoma are also correlated with increased activation of p70S6K (Filonenko et al., 2004; Sahin et al., 2004; Nozawa et al., 2007). We found that active p70S6K was able to bind and cross-link actin filaments and regulate actin organization in HepG2 liver cancer cells (Supplementary Figure 5), further suggesting that the cytoskeletal function of p70S6K we propose here may have broad implications for other tumor cell types as well.

In summary, the present study reveals the novel identification of the localization and function of p70S6K in the actin cytoskeleton. The results show that p70S6K has pivotal roles in regulating metastatic progression, and opens new areas for further investigation. Such findings greatly advance our understanding of the role of p70S6K in oncogenesis and
highlight that usefulness of targeting $p70^{66K}$ to impede metastasis in ovarian cancer.
Materials and methods

Cells and cell culture

Institutional approval for experimentation with human tissues was obtained prior to this study. OSE-529, OSE-545, and OSE-547 were obtained from ovaries at laparoscopy from women having surgery for non-malignant gynecologic diseases. The human ovarian carcinoma cell lines CaOV-3 and SKOV-3 were gifts from Dr. N. Auersperg (University of British Columbia, Vancouver, B. C., Canada). Cells were cultured in media 199:MCDB105 supplemented with 10% fetal bovine serum (FBS) for OSE and 5% FBS for ovarian cancer cell lines. HepG2 human liver cancer cell line was maintained in DME containing 5% FBS. Cells were grown in humidified atmosphere of 5% CO₂ at 37°C.

DNA constructs and transfection

N17Rac1 and L61Rac1 constructs were kindly provided by Dr. A. Hall (Memorial Sloan-Kettering Cancer Center, New York, NY) (Olson et al., 1995). N17Cdc42, V12Cdc42, N19RhoA, and V14RhoA were obtained from UMR cDNA Resource Center (Missouri, MO). The myc-tagged constitutively active p70S6K (ΔN₅₄ΔC₁₀₄ and D₃E-E₃₉₈) were gifts from Dr. G. Thomas (Genome Research Institute, University of Cincinnati, Cincinnati, OH) (Jefferies et al., 1997). GFP-tagged D₃E-E₃₉₈ was constructed by
subcloning into pEGFP vector (Clontech). To express cDNA constructs, cells were transiently transfected with 1 µg of plasmid DNA per well in 6-well plates using Lipofectamine 2000 reagent (Invitrogen).

Small interfering RNA

p70S6K-specific siRNA (#3, 5'-GACAAAAUCCUCAAUGUA-3'; #4, 5'-GCAGGAGUGUUUGACAUAG-3') (Pon et al., 2008), PAK1-specific siRNA (#1, 5'-CAUCAAAUAUCACUAAGUC-3'; #2, 5'-CAACAAAGAAACAAUCA-3'), and a nonspecific duplex oligo (5'-GGCTACGTCCAGGAGCGA-3') as a negative control were purchased from Dharmacon (Lafayette, CO). Cells were transfected overnight with 20 nM of siRNA using siLectFect (Bio-Rad) following the manufacturer’s instruction.

Western blotting

Equal amounts of cell lysates were resolved by SDS-PAGE. The samples were incubated overnight at 4°C with the following primary antibodies: anti-c-myc (clone 9E10) (1:1,500), anti-phospho-p70S6K (Thr389) (1:1,000), anti-p70S6K (1:1,000), anti-phospho-S6 (Ser235/236) (1:1,000), anti-S6 (1:1,000), anti-phospho-PAK1 (Ser144)/PAK2 (Ser141) (1:1,000), anti-PAK1 (1:1,000), (Cell Signaling), anti-Rac1
(clone 23A8) (1:1,000), anti-Cdc42 (1:250), anti-RhoA (clone 55) (1:250) (Upstate), and anti-β-actin (1:1,500) (Sigma). Proteins were visualized by enhanced chemiluminescence (Amersham).

**Fluorescence microscopy**

To detect F-actin, cells were fixed in 4% paraformaldehyde in PBS. Cells were permeabilized with 0.1% Triton X-100, blocked with 5% BSA, and then incubated with Texas red-conjugated phalloidin (4 units/ml; Molecular Probes) for 1 h at room temperature. Images were observed by confocal microscopy using a Leica DMRB. In some cases, cells were treated with 1 μM cytochalasin D (Calbiochem) (known to disrupt actin filaments) for 30 min prior to fixation.

**Actin binding assay**

Binding of p70S6K to actin was tested in a cosedimentation assay according to the manufacturer’s instructions (Cytoskeleton). Briefly, cell lysates were first precleared by centrifugation at 800 g for 6 min and then incubated in the presence or absence of polymerized rabbit α-skeletal muscle actin at room temperature for 30 min. The reaction mixtures were centrifuged at 150,000 g for 90 min. BSA, which does not bind actin, and
α-actinin, an actin-binding protein, were used as negative and positive controls, respectively. The supernatant and pellet were separated and equal amounts were analyzed by Western blotting using anti-phospho-p70<sub>S6K</sub> antibody.

To examine whether p70<sup>S6K</sup> directly interacts with actin, purified recombinant human active p70<sup>S6K</sup> (R&D Systems) was used. After 1 h incubation at room temperature, actin filaments and bound purified proteins were pelleted by centrifugation at 100,000 g for 1 h at 20<sup>°</sup>C. Equal amounts of the pellet and supernatant were analyzed by SDS-PAGE and Coomassie Blue staining.

**Actin cross-linking assay**

Precleared cell lysates or purified p70<sup>S6K</sup> (R&D Systems) was added to 4.5 μM freshly prepared F-actin for 1 h at room temperature, and was then centrifuged at 14,000 g for 1 min to sediment bundled F-actin, the linear, unbundled F-actin remains in the supernatant. Equal amounts of the pellet and supernatant were analyzed by SDS-PAGE and the gel was stained with Coomassie Blue.

**Light scattering and electron microscopy**

Changes in light scattering of unlabeled actin was monitored by 90° light scattering at
405 nm (Perkin Elmer). The change of light scattering was recorded after addition of polymerization buffer to purified p70S6K and G-actin. Electron microscopy was performed on samples after actin polymerization was complete, as monitored by light scattering. Samples were fixed by 0.05% glutaraldehyde, spotted onto carbon-coated formvar grids, and negative stained with 2% uranyl acetate. Images were recorded on a CCD camera with a Philips EM208s transmission electron microscope (Eindhoven, The Netherlands).

**Actin polymerization assay**

Purified G-actin (2.5 μM, 10% pyrene-labeled) was incubated with purified p70S6K for 30 min, and polymerization was initiated with 0.1 volume of 10x polymerization buffer. To measure cofilin-induced depolymerization, 1 μM polymerized filaments were incubated with purified p70S6K for 30 min, and actin depolymerization was induced by the addition of 1 μM recombinant purified human cofilin (Cytoskeleton). The change in fluorescence was monitored over time with excitation at 355 nm and emission at 405 nm using a Victor X4 plate reader (Perkin Elmer).
**Cell polarity and migration analysis**

Cells were cultured to confluency and scraped using a pipette tip. Cells at the wound edge with Golgi (anti-GM130, Sigma) polarized to the front-facing 120° sector were scored as positive for polarization. Migration assay was performed using a 24-well Transwell inserts (8 μm pore size; Millipore). Cells (1.5 × 10^4 per well) were placed in the upper chamber, and 5% serum was placed in the lower chamber as a chemoattractant. The migratory phenotype was determined by counting the cells that had migrated to the lower side of the filter. Results were presented as the mean cell number of five fields ± SD of triplicate experiments.

**Rac1, Cdc42, and RhoA activity assay**

Pull-down assays were performed to isolate the active GTP-bound form using the Rac1/Cdc42 and RhoA activation assay kits (Upstate) following the manufacturer’s instructions. Briefly, 10 μg of agarose conjugated GST-PAK-1 PBD fusion protein were added to the lysate and rotated for 1 h at 4°C. The beads were washed three times, eluted with sample buffer and immunoblotted for either Rac1 or Cdc42. A similar assay, using the Rhoketin Rho binding domain (RBD) as a GST fusion protein, was used to measure RhoA activation. For negative and positive controls, cell extracts were incubated with 1
mM GDP and 100 µM GTPγS, respectively.

Statistical analysis

Data were expressed as mean ± SD. Experiments were performed three times. Statistical significance was evaluated with Student's *t* test. *P* < 0.05 was considered to be significant.

Acknowledgments

We thank Drs N Auersperg, G Thomas, and A Hall for providing cell lines and cDNA constructs. This work was supported by the Research Grant Council grant HKU 7599/05M and the HKU Outstanding Young Research Award (AST Wong).

Figure Legends

Figure 1  p70\textsuperscript{S6K} activation induces reorganization of the actin cytoskeleton. (a) CaOV-3 and SKOV-3 cells were transfected with constitutively active p70\textsuperscript{S6K} (ΔN\textsubscript{54}ΔC\textsubscript{104} or D\textsubscript{3}E-E\textsubscript{380}). Cells were fixed and visualized by phase microscopy, or stained for F-actin using Texas red-conjugated phallloidin and observed by confocal microscopy. Whole cell lysates were analyzed for the levels of phosphorylated (p-) and total forms of S6 by Western blot analysis. (b) Cells were transfected with nonspecific (NS) or p70\textsuperscript{S6K} siRNA or pretreated with rapamycin (Rp; 20 nM). Cells were then stimulated with HGF (10 ng/ml) for 1 h, fixed, and stained with Texas red-conjugated phallloidin. Expression of p70\textsuperscript{S6K} was analyzed by Western blotting. β-actin was included as a loading control. Arrows indicate representative lamellipodia (↑) and filopodia (▲). Bar, 10 μm. Quantification of lamellipodia/filopodia is expressed as the mean number per 200 cells. Data are mean ± SD of three independent experiments. *, P < 0.05 compared with control or HGF and NS siRNA treated cells.

Figure 2  Directed cell migration is impaired in p70\textsuperscript{S6K} knockdown cells. (a) Nonspecific (NS) or p70\textsuperscript{S6K} siRNA cells were plated for the scrape-wound assay. Six hours after wounding, cells were fixed and stained with a Golgi marker (anti-GM130, red)
and nucleus (DAPI, blue). Percentage of cells exhibiting reoriented Golgi into the 120° sector facing the wound was quantified. (b) Cells were seeded onto transwell inserts for cell migration assays. Quantification of migrated cells is expressed as the mean number per five fields. Experiments were repeated three times, and data are shown as mean ± SD. *
P < 0.05 compared with control or HGF and NS siRNA treated cells.

Figure 3  p70S6K directly binds to actin. (a) CaOV-3 cell lysates were allowed to react with F-actin and then sedimented at 150,000 g (high speed). Equal amounts of pellets and supernatants were analyzed by SDS-PAGE and blotted with anti-phospho (p)-p70S6K. (b) F-actin was incubated with different concentrations of purified active p70S6K (0.05, 0.1, 0.2 μM) followed by high-speed cosedimentation. Equivalent samples of pellets and supernatants were resolved by SDS-PAGE and proteins were visualized by Coomassie Blue staining. (c) p70S6K was mixed with F-actin buffer and centrifuged in either the presence (+) or absence (-) of F-actin. (d) Cells were treated with HGF (10 ng/ml) or transfected with constitutively active p70S6K (D3E-E389) or (e) pretreated with cytochalasin D (Cyto D; 1 μM) for 30 min and then stimulated with HGF. Cells were fixed and stained with anti-p-p70S6K (green), anti-myc (green), or phalloidin (red) and observed by confocal microscopy. Data shown represent three independent experiments.
performed with similar results. Bar, 5 μm.

**Figure 4**  p70S6K cross-links and stabilizes F-actin. (a) CaOV-3 cell lysates were allowed to react with F-actin and sedimented at 14,000 g. Under this condition, the linear, unbundled F-actin is in the supernatant, whereas bundled F-actin sediment. Both pellet and supernatant were separated on SDS-PAGE and analyzed by Western blotting with anti-p-p70S6K. (b) F-actin (4.5 μM) was incubated with increasing concentrations of p70S6K (0.05, 0.1 μM) and actin cross-linking assays were performed. (c) F-actin (2.5 μM) alone (○) or incubated with increasing concentrations of p70S6K (■ 0.05 μM; ▲ 0.1 μM) was monitored at 405 nm. (d) Negatively stained electron micrographs of F-actin in the absence or presence of 0.1 μM purified p70S6K. Bar, 0.2 μm.

**Figure 5**  p70S6K inhibits cofilin-induced actin depolymerization. (a) G-actin (2.5 μM, 10% pyrene-labeled) was polymerized with the addition of actin polymerization buffer in the presence or absence of p70S6K (0.1 μM). (b) Pyrene-labeled actin filament disassembly was induced by addition of 1 μM recombinant purified human cofilin with or without 0.1 μM purified p70S6K.
Figure 6  Specific activation of p70S6K on Rac1 and Cdc42, but not RhoA. (a) CaOV-3 cells were stimulated with HGF (10 ng/ml) for the indicated times (in minutes) or transfected with constitutively active p70S6K (D3E-E389). (b) In some cases, cells were transfected with nonspecific (NS) or p70S6K siRNA or (c) treated with rapamycin (Rp) before HGF stimulation. Lysates were analyzed for GTPase activation using pull-down assays as described in Materials and methods. GTP-bound (active) Rac1, Cdc42, and RhoA were examined by Western blotting. Alternatively, lysates were resolved in SDS-PAGE and blotted with anti-phospho (p)-p70S6K, total p70S6K, and Rac1, Cdc42 and RhoA. GTPγS served as a positive control and GDP was a negative control. The blots represent three independent experiments performed with similar results.

Figure 7  Rac1 and Cdc42 mediate p70S6K-induced actin reorganization. (a) CaOV-3 cells were cotransfected with GFP-tagged constitutively active p70S6K (D3E-E389) and dominant negative Rac1 (N17Rac1) or Cdc42 (N17Cdc42) or (b) constitutively active Rac1 (L6Rac1) or Cdc42 (V12Cdc42). F-actin was visualized with Texas Red phalloidin. (c) Cells were treated with HGF (10 ng/ml), fixed, and stained with anti-p-p70S6K (green) or anti-Rac1/Cdc42 (red) Bar, 5 μm. Quantification of lamellipodia/filopodia is expressed as the mean number per 200 cells of three independent experiments. *, \( P < 0.05 \)
compared with cells expressing D$_3$E-E$_{389}$ or control cells.

**Figure 8**  PAK1 is required for p70$^{S6K}$ function. (a) CaOV-3 cells were transfected with constitutively active p70$^{S6K}$ (D$_3$E-E$_{389}$) (*left*), nonspecific (NS) siRNA, or p70$^{S6K}$ siRNA before HGF stimulation (10 ng/ml) (*right*). Lysates were analyzed by Western blot using anti-phospho-PAKs. (b) Cells were cotransfected with GFP-tagged D$_3$E-E$_{389}$ and NS siRNA or PAK1 siRNA. F-actin was visualized with Texas Red phalloidin. Bar, 5 μm. Quantification of lamellipodia/filopodia is expressed as the mean number per 200 cells. (c) Cells were cotransfected with D$_3$E-E$_{389}$ and dominant negative Rac1 (N17Rac1), Cdc42 (N17Cdc42), NS siRNA, or PAK1 siRNA. Transfected cells were seeded onto transwell inserts for cell migration assays. Quantification of migrated cells is expressed as the mean number per five fields. Data are mean ± SD of three independent experiments. *, $P < 0.05$ compared with cells expressing D$_3$E-E$_{389}$.

**Figure 9**  A model proposed to illustrate p70$^{S6K}$ in actin cytoskeleton reorganization and migration. p70$^{S6K}$ directly and indirectly reorganizes the actin cytoskeleton through cross-linking and stabilizing filaments and Rac1- and Cdc42-activating activities, which eventually leading to polarized actin structure and directed cell migration.
Supplementary Figure Legends

Figure 1  Effects of HGF and constitutive activation of p70S6K on cell proliferation. Control, HGF-treated (10 ng/ml), vector, or constitutively active p70S6K (D3E-E389)-transfected cells cultured for 24 h were collected for MTT assay. A tetrazolium dye (MTT) [3-(4,5-dimethylthiazol-2-y1)-2,5-diphenyltetrazolium bromide] was added to a final concentration of 1 mg/ml, and plates were incubated for 4 h. The conversion of MTT to formazan was monitored by the absorbance of each well at 570 nm with 630 as the reference wavelength. The absorbance of control cells was arbitrarily set as 1, and cell growth was expressed as the fold changes compared with the control. Experiments were repeated three times, and data are shown as mean ± SD.

Figure 2  p70S6K binds actin and promotes Rac1 and Cdc42 activation in SKOV-3 cells. (a) Cells were transfected with myc-tagged constitutively active p70S6K (D3E-E389), stained with phalloidin (red) or anti-myc (green), and observed by confocal microscopy. Bar, 5 μm. Polymeric α-skeletal muscle actin was incubated with cell lysates for 30 min followed by (b) high-speed (150,000 g) or (c) low-speed (14,000 g) actin cosedimentation assays. Equal amounts of pellets and supernatants were detected by Western blotting with anti-phospho (p)-p70S6K. (d) Cells were transfected with
nonspecific (NS) or p70S6K siRNA or (c) treated with rapamycin before HGF stimulation (10 ng/ml) and subjected to the pull-down assays. GST-bound (active) Rac1, Cdc42 and RhoA were analyzed by Western blot. GTPγS served as a positive control and GDP was a negative control.

**Figure 3** Rho GTPases are not required for p70S6K activation. (a) CaOV-3 cells transfected with control or myc-tagged dominant negative Rac1 (N17Rac1), Cdc42 (N17Cdc42), or RhoA (N19RhoA) were analyzed by Western blotting after stimulation with HGF (10 ng/ml) for 1 h. (b) Lysates from CaOV-3 cells expressing control or constitutively active Rac1 (L61Rac1), Cdc42 (V12Cdc42), or RhoA (V14RhoA) were subjected to Western blotting. Membranes were probed initially for phospho (p)-p70S6K, followed by stripping and reprobing with antibodies to p70S6K. β-actin was included as a loading control. Exogenously expressed myc-tagged Rac, Cdc42, and Rho proteins were detected using a myc antibody.

**Figure 4** Effect of p70S6K activation on the actin cytoskeleton of normal OSE. (a) OSE-529, OSE-545, and OSE-547 cells were transfected with myc-tagged constitutively active p70S6K (D3E-E389). Cells were fixed and visualized by phase microscopy, or (b)
stained for F-actin with Texas red-conjugated phalloidin (red) or D3E-E389 with anti-myc (green) and observed by confocal microscopy. Bar, 5 μm.

**Figure 5**  
p70⁵⁶K binds to and cross-links F-actin and regulates actin organization in HepG2 cells.  
(a) Cells were transfected with constitutively active p70⁵⁶K (D₃E-E₃₈₉), stained with phalloidin, and observed by confocal microscopy. Bar, 5 μm. Polymeric α-skeletal muscle actin was incubated with cell lysates for 30 min followed by (b) high-speed (150,000 g) or (c) low-speed (14,000 g) actin cosedimentation assays. Equal amounts of pellets and supernatants were detected by Western blotting with anti-phospho (p)-p70⁵⁶K. (d) Cells were cotransfected with D₃E-E₃₈₉ and dominant negative Rac1 (N17Rac1) or Cdc42 (N17Cdc42). F-actin was visualized with Texas Red phalloidin.
