The present invention relates to the inhibition of Hepatitis B virus (HBV) replication by RNA molecules of the present invention. Specifically, the RNA molecules of the present invention are double-stranded ribonucleic acid molecules (dsRNA). Specifically, the invention relates to small interfering RNAs (siRNA) which are double-stranded RNAs that direct the sequence-specific degradation of messenger RNA in mammalian cells. The invention relates to development of a new anti-HBV therapy by inhibition of Hepatitis B Virus (HBV) replication using stably-expressed short hairpin RNAs (shRNA), which degrade HBV pregenomic RNA and message RNAs. Included are methods of treatment of cancer by the administration of RNA molecules of the present invention in combination with surgery, alone or in further combination with standard and experimental chemotherapies, hormonal therapies, biological therapies/immunotherapies and/or radiation therapies.

INHIBITION OF HEPATITIS B VIRUS (HBV) REPLICATION BY RNA INTERFERENCE

This application claims priority benefit to U.S. provisional application No. 60/471,903, filed May 19, 2003, which is incorporated herein by reference in its entirety.

1. INTRODUCTION

The present invention relates to the inhibition of Hepatitis B virus (HBV) replication by RNA molecules of the present invention. Specifically, the RNA molecules of the present invention are double-stranded ribonucleic acid molecules (dsRNA). Specifically, the invention relates to small interfering RNAs (siRNA), which are double-stranded RNAs that direct the sequence-specific degradation of messenger RNA in mammalian cells. The invention relates to development of a new anti-HBV therapy by inhibition of Hepatitis B Virus (HBV) replication using stably-expressed short hairpin RNAs (shRNA), which degrade HBV pregenomic RNA and message RNAs. Included are methods of treatment of cancer by the administration of RNA molecules of the present invention in combination with surgery, alone or in further combination with standard and experimental chemotherapies, hormonal therapies, biological therapies/immunotherapies and/or radiation therapies.

2. BACKGROUND OF THE INVENTION

The major challenges for anti-HBV therapy are the low efficacy of current drugs and the occurrence of drug resistant HBV mutations. Liu, 2001, Clin Liver Dis. 5:361–379. There are an estimated 400 million chronic Hepatitis B virus (HBV) infected patients worldwide, and over one million people die of liver failure or HBV-associated hepatocellular carcinoma (HCC) annually. The major challenges for anti-HBV therapy are the low efficacy of current drugs and the occurrence of drug resistant HBV mutations. Only about twenty percent of the patients benefit from combination therapy with interferon-alpha and lamivudine. It is therefore important to develop a new strategy to treat HBV patients. A drug with new target sites or independent metabolic pathways may overcome these shortcomings.

3. SUMMARY

The present invention is based on the observation of the present inventors that stably-expressed 21-mer short hairpin RNAs (shRNA) inhibit Hepatitis B Virus (HBV) replication. shRNAs degrade targets such as HBV pregenomic RNA and message RNAs. These targets include HBV reverse-transcriptase and other sites of pregenomic RNA, including DR elements, S, and X gene. In specific embodiments, shRNAs specifically target drug binding sites (736i), the open reading frame of S antigen, polymerase (157i), the open reading frame of X protein (1694i), the DR elements on the pregenomic RNA (1592i and 1826i), or block HBV replication. The anti-HBV efficacy of siRNA is much more potent than that of lamivudine. The present inventors discovered that shRNAs can serve as efficient anti-HBV agents. The inventors also discovered that shRNAs provide synergistic effects on the inhibition of HBV replication due to different mechanisms of drug actions. In some embodiments, shRNA may be combined with current anti-HBV drugs to increase the anti-HBV efficacy. In a specific embodiment, shRNA may be combined with lamivudine and/or interferon alpha for the treatment of HBV related diseases. In other preferred embodiments, shRNAs may be used in combination with other therapy such as, but not limited to, chemotherapy or therapies using nucleotide analogs. Accordingly, the present invention also provides methods of treatment for liver failure or HBV-associated hepatocellular carcinoma (HCC). In specific embodiments, shRNAs may be mediated by viral gene delivery vector. In a specific embodiment, shRNAs may be mediated via gene therapy.

In certain embodiments, a process is provided for inhibiting expression of a target gene in hepatitis B virus. The process comprises introduction of RNA with partial or fully double-stranded character into the cell affected by the virus or into the extracellular environment. Inhibition is specific in that a nucleotide sequence from a portion of the target gene is chosen to produce inhibitory RNA. The present invention is effective in producing inhibition of gene expression, specific to the targeted gene, and allowing inhibition of many different types of target gene in HBV.

Depending on the particular target gene and the dose of double stranded RNA material delivered, the method of the invention may provide partial or complete loss of function for the target gene of HBV. A reduction or loss of gene expression may be at least 99%, 90%, 85%, 80%, 75%, 70%, 65%, 60%, 55%, 50%, 45%, 40%, 45%, 50%, 60%, 70%, 75%, 80%, 85%, 90%, 99%. Quantitation of gene expression in a cell may show inhibition at the level of accumulation of target mRNA or translation of target protein.

The RNA molecules of the present invention may comprise one or more strands of polymerized ribonucleotides; it may include modifications to either the phosphate-sugar backbone or the nucleoside. The double-stranded structure may be formed by a single self-complementary RNA strand or two complementary RNA strands. RNA duplex formation may be initiated either inside or outside the infected cell. The RNA may be introduced in an amount which allows delivery of at least one copy per infected cell. Higher doses of double-stranded material may yield more effective inhibition. Inhibition is sequence-specific in that nucleotide sequences corresponding to the duplex region of the RNA are targeted for genetic inhibition. RNA containing a nucleotide sequences identical to a portion of the target gene is preferred for inhibition. RNA sequences with insertions, deletions, and single point mutations relative to the target sequence may be effective for inhibition. Thus, sequence identity may optimized by alignment algorithms known in the art and calculating the percent difference between the nucleotide sequences. Alternatively, the duplex region of the RNA may be defined functionally as a nucleotide sequence that is capable of hybridizing with a portion of the target gene transcript.

The RNA molecules of the present invention may be synthesized either in vivo or in vitro. Endogenous RNA polymerase of the cell infected with HBV may mediate transcription in vivo, or cloned RNA polymerase can be used for transcription in vivo or in vitro. For transcription from a transgene in vivo or via an expression construct, a regulatory region may be used to transcribe the RNA strand (or strands).

The RNA may be directly introduced into the cell (i.e., intracellularly), or introduced extracellularly into a cavity, interstitial space, into the circulation of a subject in need of the treatment.

FIG. 3. The synergistic effect of shRNA and lamivudine. A synergistic effect on the inhibition of HBV replication was observed when shRNA stably-expressed cells were cultured in the 3TC containing medium.

5. DETAILED DESCRIPTION

The present invention relates to the inhibition of Hepatitis B virus (HBV) replication using RNA molecules of the present invention. Specifically, the RNA molecules of the present invention are double-stranded ribonucleic acid molecules (dsRNA). Specifically, the invention relates to small interfering RNAs (siRNA) which are double-stranded RNAs that direct the sequence-specific degradation of messenger RNA in mammalian cells. The invention relates to development of a new anti-HBV therapy by inhibition of Hepatitis B Virus (HBV) replication using stably-expressed short hairpin RNAs (shRNA), which degrade HBV pregenomic RNA and message RNAs.

5.1. Inhibition of HBV Genes

Disruption of the HBV life cycle will inhibit HBV replication. Upon infection, the partial double strand DNA of the present invention is repaired to form a 3.2-kb cccDNA, which serves as a template to transcribe overlapping RNA species including a 3.5-kb pregenomic RNA (FIG. 1A) and mRNA species (FIG. 1B) coding for reverse-transcriptase (polymerase), core, PreS, S and X proteins. Seeger et al., 2000, Microbiol Mol Biol Rev. 64:51–68. These RNAs are then translated into HBV proteins or reverse-transcribed into HBV DNA. All the HBV proteins play important roles in HBV transcriptional regulation, viral package, reverse-transcription and viral DNA recycling. During HBV replication, the special structure DR1 and DR2 (FIG. 1A) in the pregenomic RNA are the essential cis-elements for viral package, primer translocation and reverse-transcription.

shRNA duplexes specifically target DR elements and regions encoding HBV proteins and are capable of inhibiting HBV replication by degradation of viral RNA species. A series of shRNA expression plasmids were generated. The synthetic DNA oligos encoding shRNAs were annealed and cloned downstream of U6 promoter for the expression of double-stranded siRNA (FIG. 2A). Paul et al., 2002, Nat Biotechnol 20:505–508. These shRNAs’ target sites on the HBV RNAs are shown in FIG. 1B. 871 targets the ORF of PreS and Polymerase, 1571, 4511, 6600 and 7361 target the ORF of S and polymerase, including the nucleotide analog drugs’ target sites (6601 and 7361). Fu et al., 1998, Biochem Pharmacol 55:1567–1572. 15921 and 18261 target the ORF of X, and the DR2 and DR1 elements in the pregenomic RNA respectively. 16941 targets the ORF of X, and 23101 targets the ORF of core and polymerase in the pregenomic RNA. 29791 targets the polymerase and PreS coding region. The empty vector or shRNA expression vectors were transfected into HepG2 cells and shRNA stably-expressed cells were obtained by selection with G418. pHBV, a plasmid containing HBV-adr genome for generation of HBV viruses, and luciferase expression plasmid pDM1948 were cotransfected into HepG2 cells. Fu et al., 1997, Chin. J. Virol. 13:215–223. The total RNA was isolated 36 hours post-transfection and reverse-transcription PCR experiments were performed. The HBV RNA and luciferase mRNA was quantified by real-time RT-PCR. The expressed shRNAs markedly reduced the HBV RNA level (FIG. 2B). The stably-expressed 871, 4511, 15921, 18261 and 23101 reduced HBV RNA by up to 80%, while the other stably-expressed siRNAs reduced HBV RNA by over 90% (FIG. 2B). The stably-expressed siRNAs are potent agents for the cleavage of HBV RNA, which inhibit HBV replication.

Replication assays were performed to determine the effectiveness of the siRNA. The stable cells 1571, 7361, 15921, 16941 and 18261 were cotransfected with pHBV and pDM1948. The cells were harvested 72 hours post-transfection and lysed without breaking HBV particles. A small fraction of cell lysates was used for the measurement of luciferase activity using a luciferase kit (Promega, Wis.). The HBV DNA in the core particles was isolated from the remaining cell lysates and quantified by real-time PCR. He et al., 2002, Biochem Biophys Res Commun 295:1102–1107. The HBV titer was not sized with luciferase activity. All the stably-expressed shRNA potentially inhibited HBV replication. The relative HBV titer generally dropped by 90% to 98% (FIG. 2C).

In a specific embodiment, shRNA may be combined with current anti-HBV drugs to increase the anti-HBV efficacy. To test whether shRNA with lamivudine has synergistic effects on the inhibition of HBV replication, pHBV and pDM1948 were cotransfected into the stably-expressed...
shRNA cells to observe HBV replication. After transfection, lamivudine was put in the culture medium and maintained for 6 days. It was found that shRNA combined with lamivudine (3TC) exhibited synergistic effects to inhibit HBV replication (FIG. 3). In a typical experiment, shRNA with lamivudine reduced HBV titer four times more than lamivudine alone, and two times more than shRNA alone.

Our findings provide evidence for the development of an anti-HBV gene therapy using proper gene delivery vectors, which may enhance the anti-HBV efficacy and overcome drug resistance.

The new therapy can also be combined with chemotherapy. RNAi can specifically silence gene expression through repression of translation when the sense strand in the dsRNA is incompletely paired with the target RNA, or by mediation of target RNA cleavage when the anti-sense strand in the dsRNA is completely paired with the target RNA. A point mutation in HBV genome leads to drug resistance. Stably-expressed shRNAs targeting either drug binding sites (736I), the ORF of S antigen and polymerase (157I), the ORF of X protein (169S), or the DR elements on the pregenomic RNA (152S and 182S), block HBV replication. shRNA stably-expressed cells treated with lamivudine exhibited synergistic effects on the inhibition of HBV replication. Long-term expression of shRNA mediated by viral gene delivery vehicle will have a great potential in anti-HBV gene therapy, and can be used in the combination therapy with the nucleotide analogs.

5.2. Methods for Inhibiting Gene Expression

Targeted inhibition of gene expression may be implemented via the use of polynucleotide compounds, such as but not limited to, antisense polynucleotides, ribozymes, RNA interference molecules, triple helix polynucleotides and the like, where the nucleotide sequence of such compounds are related to the nucleotide sequences of DNA and/or RNA of genes that are involved in the initiation, transcription, translation or replication. Antisense technology has been the most commonly described approach in protocols to achieve gene-specific interference. For antisense strategies, stoichiometric amounts of single-stranded nucleic acid complementary to the messenger RNA for the gene of interest are introduced into the cell. Another method for engineered interference is based on a triple helical nucleic acid structure. This approach relies on the ability of certain nucleic acid populations to adopt a triple-stranded structure.

In preferred embodiments, an RNA interference (RNAi) molecule is used to decrease gene expression in HBV. RNA interference (RNAi) refers to the use of double-stranded RNA (dsRNA) or small interfering RNA (siRNA) to suppress the expression of a gene comprising a related nucleotide sequence. RNAi is also called post-transcriptional gene silencing (or PTGS). Since the only RNA molecules normally found in the cytoplasm of a cell are molecules of single-stranded mRNA, the cell has enzymes that recognize and cut dsRNA into fragments containing 21-25 base pairs (approximately two turns of a double helix and which are referred to as small interfering RNA or siRNA). The antisense strand of the fragment separates enough from the sense strand so that it hybridizes with the complementary sense sequence on a molecule of endogenous cellular mRNA. This hybridization triggers cutting of the mRNA in the double-stranded region, thus destroying its ability to be translated into a polypeptide. Introducing dsRNA corresponding to a particular gene thus knocks out the cell’s own expression of that gene in particular tissues and/or at a chosen time.

Double-stranded (ds) RNA can be used to interfere with gene expression in mammals. dsRNA is used as inhibitory RNA or RNAi of the function of a nucleic acid molecule of the invention to produce a phenotype that is the same as that of a null mutant of a nucleic acid molecule of the invention (Wienmeier & Zernicka-Goetz, 2000, Nature Cell Biology 2: 70-75).

Alternatively, siRNA can be introduced directly into a cell to mediate RNA interference (Elbashir et al., 2001, Nature 411:494-498). Many methods have been developed to make siRNA, e.g., chemical synthesis or in vitro transcription. Once made, the siRNAs are introduced into cells via transient transfection. A number of expression vectors have also been developed to continually express siRNAs in transiently and stably transfected mammalian cells (Brummelkamp et al., 2002 Science 296:550–553; Sui et al., 2002, PNAS 99(6):5515-5520; Paul et al., 2002, Nature Biotechnol. 20:505–508). Some of these vectors have been engineered to express small hairpin RNAs (shRNAs), which get processed in vivo into siRNA-like molecules capable of carrying out gene-specific silencing. Another type of siRNA expression vector encodes the sense and antisense siRNA strands under control of separate pol III promoters (Miyagishi and Taira, 2002, Nature Biotechnol. 20:497–500). The siRNA strands from this vector, like the shRNAs of the other vectors, have 3’ thymidine termination signals. Silencing efficacy by both types of expression vectors was comparable to that induced by transiently transfecting siRNA.

The RNA may comprise one or more strands of polymerized ribonucleotide. It may include modifications to either the phosphate-sugar backbone or the nucleoside. For example, the phosphodiester linkages of natural RNA may be modified to include at least one of a nitrogen or sulfur heterocyclic. Modifications in RNA structure may be tailored to allow specific genetic inhibition while avoiding a general panic response in some organisms which is generated by dsRNA. Likewise, bases may be modified to block the activity of adenosine deaminase. RNA may be produced enzymatically or by partial or total organic synthesis, any modified ribonucleotide can be introduced by in vitro enzymatic or organic synthesis.

The double-stranded structure may be formed by a single self-complementary RNA strand or two complementary RNA strands. RNA duplex formation may be initiated either inside or outside the cell. The RNA may be introduced in an amount which allows delivery of at least one copy per cell. Higher doses (e.g., at least 5, 10, 100, 500 or 1000 copies per cell) of double-stranded material may yield more effective inhibition; lower doses may also be useful for specific applications. Inhibition is sequence-specific in that nucleotide sequences corresponding to the duplex region of the RNA are targeted for genetic inhibition. The RNA molecule may be at least 10, 12, 15, 20, 21, 22, 23, 24, 25, 30, nucleotides in length.

RNA containing a nucleotide sequences identical to a portion of the target gene are preferred for inhibiting RNA sequences with insertions, deletions, and single point mutations relative to the target sequence have also been found to be effective for inhibition. Thus, sequence identity may be optimized by sequence comparison and alignment algorithms known in the art (see Gribskov and Devereux, Sequence Analysis Primer, Stockton Press, 1991, and references cited therein) and calculating the percent difference between the nucleotide sequences by, for example, the
Smith-Waterman algorithm as implemented in the BESTFIT software program using default parameters (e.g., University of Wisconsin Genetic Computing Group). Greater than 90% sequence identity, or even 100% sequence identity, between the inhibitory RNA and the portion of the target gene is preferred. Alternatively, the duplex region of the RNA may be defined functionally as a nucleotide sequence that is capable of hybridizing with a portion of the target gene transcript (e.g., 400 mM NaCl, 40 mM PIPES pH 6.4, 1 mM EDTA, 50°C or 70°C hybridization for 12–16 hours; followed by washing). The length of the identical nucleotide sequences may be at least 25, 50, 100, 200, 300 or 400 bases.

One hundred percent sequence identity between the RNA and the target gene is not required to practice the present invention. Thus the invention has the advantage of being able to tolerate sequence variations that might be expected due to genetic mutation, strain polymorphism, or evolutionary divergence.

RNA may be synthesized either in vivo or in vitro. Endogenous RNA polymerase of the cell may mediate transcription in vivo, or cloned RNA polymerase may be used for transcription in vivo or in vitro. For transcription from a transgene in vivo or an expression construct, a regulatory region (e.g., promoter, enhancer, silencer, splice donor and acceptor, polyadenylation) may be used to transcribe the RNA strand (or strands). Inhibition may be targeted by specific transcription in an organ, tissue, or cell type; stimulation of an environmental condition (e.g., infection, stress, temperature, chemical inducers); and/or engineering transcription at a developmental stage or age. The RNA strands may or may not be polyadenylated; the RNA strands may or may not be capable of being translated into a polypeptide by a cell’s translational apparatus. RNA may be chemically or enzymatically synthesized by manual or automated reactions. The RNA may be synthesized by a cellular RNA polymerase or a bacteriophage RNA polymerase (e.g., T3, T7, SP6). The use and production of an expression construct are known in the art (see also WO 97/3216; U.S. Pat. Nos. 5,593,874, 5,698,425, 5,712,135, 5,789,214, and 5,804,693; and the references cited therein). If synthesized chemically or by in vitro enzymatic synthesis, the RNA may be purified prior to introduction into the cell. For example, RNA can be purified by a mixture by extraction with a solvent or resin, precipitation, electrophoresis, chromatography, or a combination thereof. Alternatively, the RNA may be used with or a minimum of purification to avoid losses due to sample processing. The RNA may be dried for storage or dissolved in an aqueous solution. The solution may contain buffers or salts to promote annealing, and/or stabilization of the duplex strands.

RNA may be directly introduced into the cell (i.e., intracellularly); or introduced extracellularly into a cavity, interstitial space, into the circulation of an organism, introduced orally, or may be introduced by bathing an organism in a solution containing the RNA. Physical methods of introducing nucleic acids, for example, injection directly into the cell or extracellular injection into the organism, may also be used. Vascular or extravascular circulation, the blood or lymphatic system, and the cerebrospinal fluid are sites where the RNA may be introduced.

Physical methods of introducing nucleic acids include injection of a solution containing the RNA, bombardment by particles covered by the RNA, soaking the cell or organism in a solution of the RNA, or electroporation of cell membranes in the presence of the RNA. A viral construct packaged into a viral particle would accomplish both efficient introduction of an expression construct into the cell and transcription of RNA encoded by the expression construct. Other methods known in the art for introducing nucleic acids to cells may be used, such as lipid-mediated carrier transport, chemical-mediated transport, such as calcium phosphate, and the like. Thus the RNA may be introduced along with components that perform one or more of the following activities: enhance RNA uptake by the cell, promote annealing of the duplex strands, stabilize the annealed strands, or otherwise increase inhibition of the target gene.

The present invention may be used to introduce RNA into a cell for the treatment or prevention of disease. For example, dsRNA may be introduced into a cancerous cell or tumor and thereby inhibit gene expression of a gene required for maintenance of the carcinogenic/tumorigenic phenotype. To prevent a disease or other pathology, a target gene may be selected which is required for initiation or maintenance of the disease/pathology. Treatment would include amelioration of any symptom associated with the disease or clinical indication associated with the pathology.

Another utility of the present invention is a method of identifying gene function in an organism comprising the use of double-stranded RNA to inhibit the activity of a target gene of previously unknown function. Instead of the time consuming and laborious isolation of mutants by traditional genetic screening, functional genomics would envision determining the function of uncharacterized genes by employing the invention to reduce the amount and/or alter the timing of target gene activity. The invention could be used in determining potential targets for pharmaceuticals, understanding normal and pathological events associated with development, determining signaling pathways responsible for postnatal development/aging, and the like. The increasing speed of acquiring nucleotide sequence information from genomic and expressed gene sources, can be coupled with the invention to determine gene function in an organism.

A simple assay would be to inhibit gene expression according to the partial sequence available from an expressed sequence tag (EST) of HBV. Functional alterations in growth, development, metabolism, disease resistance, or other biological processes would be indicative of the normal role of the EST’s gene product.

Useful dsRNs of the present invention may be identified using high throughput screening (HTS). For example, duplex RNA may be produced by an amplification reaction using primers flanking the inserts of any gene library derived from the HBV virus. Inserts may be derived from genomic RNA or mRNA (e.g., cDNA and cRNA). Individual clones from the library can be replicated and then isolated in separate reactions, but preferably the library is maintained in individual reaction vessels (e.g., a 96-well microtiter plate) to minimize the number of steps required to practice the invention and to allow automation of the process. Solutions containing duplex RNAs that are capable of inhibiting the different expressed genes can be placed into individual wells positioned on a microtiter plate as an ordered array, and intact cells/organisms in each well can be assayed for any changes or modifications in behavior or development due to inhibition of target gene activity. The amplified RNA can be injected into the cell/organism containing the target gene. Alternatively, the duplex RNA can be produced by in vivo or in vitro transcription from an expression construct used to produce the library. The construct can be replicated as individual clones of the library and transcribed to produce the RNA; each clone can then be injected into the cell/organism containing the target gene. The function of the
target gene can be assayed from the effects it has on the cell/organism when gene activity is inhibited. This screening could be amenable to small subjects that can be processed in large number, for example: viruses and tissue culture cells derived from mammals.

5.3. Assay for Measuring Inhibition of Gene Expression

Inhibition of gene expression refers to the absence (or observable decrease) in the level of protein and/or mRNA product from a target gene. Specificity refers to the ability to inhibit the target gene without manifest effects on other genes of the cell. The consequences of inhibition can be confirmed by examination of the outward properties of the cell or by biochemical techniques such as RNA solution hybridization, nucleic acid protection, Northern hybridization, reverse transcription, gene expression monitoring with a microarray, antibody binding, enzyme linked immunosorbent assay (ELISA), Western blotting, radioimmunocassay (RIA), other immunoassays, and fluorescence activated cell analysis (FACS). For RNA-mediated inhibition in a cell line or whole organism, gene expression is conveniently assayed by use of a reporter or drug resistance gene whose protein product is easily assayed. Such reporter genes include acetoxyhydroxycinnamate synthase (AHAS), alkaline phosphatase (AP), beta galactosidase (lacZ), beta glucoronidase (GUS), chloramphenicol acetyltransferase (CAT), green fluorescent protein (GFP), horseradish peroxidase (HRP), luciferase (luc), nopaline synthase (NOS), octopine synthase (OCS), and derivatives thereof. Multiple selectable markers are available that confer resistance to ampicillin, bleomycin, chloramphenicol, gentamicin, hygromycin, kanamycin, lincomycin, methotrexate, phosphinothricin, pyrornycin, and tetracyclin.

5.4. Prophylactic and Therapeutic Agents

According to the invention, therapy by administration of the RNA molecules of the present invention is combined with administration of one or more therapies such as, but not limited to, chemotherapy, radiation therapies, hormonal therapies, and/or biological therapies/immunotherapies.

In a specific embodiment, the methods of the invention encompass the administration of angiogenesis inhibitors such as but not limited to: Angiostatin (plasminogen fragment); antiangiogenic antithrombin III; Angiozyme; ABT-627; Bay 12-9566; Benefin; Bevacizumab; BMS-275291; cartilage-derived inhibitor (CDI); CAI; CD59 complement segment; CEP-7055; Col 3; Combretastatin A-4; Endostatin (collagen XVIII fragment); Fibronectin fragment; Gro-beta; Halofuginone; Heparinase; Heparin hexosaccharide fragment; HMB833; Human chorionic gonadotropin (hCG); IM-862; Interferon alpha/beta/ gamma; Interferon inducible protein (IP-10); Interleukin-12; Kringle 5 (plasminogen fragment); Marimastat; Metalloproteinase inhibitors (TIMPs); 2-Methoxyestradiol; MM1 270 (CGS 27023A); McAb IMC-1C11; Neovastat; NM-3; Panzen; PI-88; Plasminogen activator inhibitor; Plasminogen activator inhibitor; Platelet factor-4 (PF-4); Prinomastat; Prolinstat 16 KD fragment; Proliferin-related protein (PRP); PTK 788/ZK 225594; Retinoinds; Solinastat; Squalamine; SS 3304; SU 5416; SU6668; SU1248; Tetracyrocoisol-S; tetrahydroxybdate; thalidomide; Thrombomodulin-1 (TSP-1); TNP-470; Transforming growth factor-beta (TGF-b); Vasculostatin; Vasoostatin (calreticulin fragment); ZD6126; ZD 6474; famesyl transferase inhibitors (FTI); and biphosphonates.

Additional examples of anti-cancer agents that can be used in the various embodiments of the invention, including pharmaceutical compositions and dosage forms and kits of the invention, include, but are not limited to: acevacin; aclurabin; acodazole hydrochloride; acronine; adzeolesin; adlesleukin; altretamine; am bromycin; am etantrone acetate; an engineutetinhemide; amsacrine; anastrozole; antrarnycin; asparaginase; asplrin; azactidine; azetepa; azotomycin; batimastat; benzoxepa; bicuthamide; bisantrene hydrochloride; bisnafide dimesylate; binzeline; bloxynic sulfate; bropinarine; busulfan; caeclinycin; calusterone; cancemide; carbetinere; carboflitin; cumasine; carboxicina hydrochloride; carzelesin; cedeefalin; chlorambucil; cirolemycin; cisplatin; cladribine; crisalrot mesylate; cyclophosphamid; cytarabine; ducarbazine; dac- timycin; daunorembin hydrochloride; decitabine; dexormaplatin; dezaquamine; dezazguanine mesylate; diaziquone; docetaxel; doxorubicin; doxorobcin hydrochloride; drolox- ifene; droxoflene citrate; drmostanonidine propionate; dua- zomycin; edatrexate; efornithine hydrochloride; elasmrit- cin; enplatin; enpromate; epipodiphicin; epirubin hydrochloride; erbolozole; esorubicin hydrochloride; estramine; estramustine; estroxyphostinophosphate sodium; etadamolide; eto- poside; etoposide phosphate; etoprine; fadrozole hydrochloride; fazarabine; feonetrine; flaxuridinone; fludarabine phosphate; fluorouracil; flurocetinone; fosfoidone; fote鼷cin sodium; gemcitabine; gemcitabine hydrochloride; hydroxy- yurea; idarubicin hydrochloride; ifosfamide; imidofosine; interleukin II (including recombinant interleukin II, or rIL2); interferon alpha-2a; interferon alpha-2b; interferon alpha-11; interferon beta-1a; interferon gamma-1b; iproplatin; irinotecan hydrochloride; lanreotide acetate; lerrozo; leuprolide acetate; lirazol hydrochloride; lome- etrexol sodium; lomustine; losaloxantrone hydrochloride; masoprex; maytansine; mefloothetine hydrochloride; megastrol acetate; melengestrol acetate; melphalan; menog- aril; mercaptopurine; methotrexate; methotrexate sodium; metoprine; meturedopa; mitidomide; mitocarcin; mito- cocin; mitogillin; mitomalcin; mitomycin; mitosper; mito- tane; mitoxantrone hydrochloride; myophenolic acid; nocodazole; nogalamycin; ormaplatin; oxirusin; paclitaxel; pegaspargase; pelomycin; pentamustine; peptomycin sul- fate; perfosfamide; pipobroman; piposulfan; piroxantrone hydrochloride; plicamycin; plomestane; portfermier sodium; portofomycin; prehmustine; procabazine hydrochloride; puromycin; pyrubicin hydrochloride; pyrazofurin; ribo- prine; rogeleinid; safingol; safingol hydrochloride; semin- sime; simtrazene; sparfosate sodium; sparsomyc; spiro- manum hydrochloride; spirostacin; spiroplatin; streptonigrin; streptozocin; sulforufen; talosmycin; tec- ogullan sodium; tegafur; teloxantrone hydrochloride; temoporfin; teniposide; teroxorine; testolactone; thiami- prine; thioguamine; thiopeta; tiazupazime; toremifene citrate; trestolate acetate; triciribine phosphate; trimetrexate; trimetrexate glucuronate; triumriolpet; tubulzo- zole hydrochloride; uracil mustard; uredepa; vapreotide; verteporfin; vinblastine sulfate; vincristine sulfate; vin- diesine; vindesine sulfate; vinfludine sulfate; vinclycinate sulfate; vinleurosine sulfate; vinorelbine tartrate; vinrostine sulfate; vinzoludine sulfate; vorozole; xeniplatin; zosostatine; zorubicin hydrochloride. Other anti-cancer drugs include, but are not limited to: 20-epi-1,25 dihydroxyvitamin D3; 5-ethynlyuracil; abiraterone; aclurabin; acylfulvinate; ade- cypenol; adzeolesin; adlesleukin; ALL-TK antagonists; altretamine; ambustamine; amidox; amifostine; aminole- vulinic acid; amrubicin; amsacrine; anergide; anastrozole; androgapholine; angiogenesis inhibitors; antagonist D;
myraporone; N-acetyldalanine; N-substituted benzamides; nafarelin; nateglin; naloxone-pentazocine; naproxin; naph-}

terpin; nartograstin; nedaplatin; nemorubicin; neridronic acid; neutral endopeptidase; nilutamide; nisamycin; nitric oxide modulators; nitrooxide antioxidant; nitrylul; O6-benzylguanamine; octreotide; okeicenone; oligonucleotides; onapristone; ondansetron; ondansetron; oral; oral cytotoxic induce; ormaplatin; oseferone; oxalipatin; oxazomycin; paclitaxel; paclitaxel analogues; paclitaxel derivatives; palatinum; palmitoylrlizoxin; pamidronic acid; panaxytril; panomifene; parabactin; pazopanib; pegaspargase; pelodesine; pentosan polysulfate sodium; pentostatin; pentozole; perflubron; perfosfamide; perillyl alcohol; phenazino- mycin; phenylacetate; phosphate inhibitors; pibrelin; pilocarpine hydrochloride; pirurubicin; piritrexim; placetin A; placetin B; plasmogen activator inhibitor; platinum complex; platinum compounds; platinum-triamine complex; porfimer sodium; porfiromycin; prednisone; propyl bis-acridone; prostaglandin J2; protosseme inhibitors; protein A-based immune modulator; protein kinase C inhibitor; protein kinase C inhibitors, microglial; protein tyrosine phosphate inhibitors; purine nucleoside phosphorylase inhibitors; purpurins; pyrazolocarcinide; pyridoxylated hemoglobin poloxymethylene conjugate; raf antagonists; raltirexed; ramotersonat; ras famesyl protein transferase inhibitors; ras inhibitors; ras-GAP inhibitor; retelipetine demethylylated; rhenium Re 186 etidronate; rhizoxin; ribozymes; RII retinamide; rogeletidine; rohitukine; romuridine; roquinimex; rubiginone B1; ruboxyl; safingol; saquinavir; SarCNU; sarcephylt A; saragambostin; Sdi 1 mimetics; semustine; senescence derived inhibitor 1; sense oligonucleotides; signal transduction inhibitors; signal transduction modulators; single chain antigen binding protein; sizofiran; sobuzoxane; sodium boracapatate; sodium phenylacetate; sororol; somatotomin binding protein; soronin; sparfloxacin; spicamycin D; spironemist; spongistatin 1; squamine; stem cell inhibitor; stem-cell division inhibitors; stipamide; stromelysin inhibitors; sulfasin; superactive vasoactive intestinal peptide antagonist; suradist; suramin; swainsonine; synthetic glycocalsaminogly- cans; tallimustine; tamoxifen methiodide; taumuretine; taz-}

arotone; teecogalan sodium; tegafur; tellururypyrilum; telomerase inhibitors; temoporfin; temozolomide; teniposide; tetrahydrocoenzyme; tetrazozone; thalidomide; thiocora- line; thienobupiostat; thienobupiostat name; thymafiasin; thymopoeitin receptor agonist; thymotrinid; thyroid stimulating hormone; tin etyl etiopurpurin; tirapazamine; titanocene bicloride; topseptin; toremifene; toptotent stem cell factor; translation inhibitors; tretoin; triacetyleuridine; triciribine; trimetrexate; tritorelin; tropisetron; turostereide; tyrosine kinase inhibitors; typhostins; UBC inhibitors; ubenimex; urogenital sinus-derived growth inhibitory factor; uron kinase receptor antagonists; vaporeotide; varibolin B; vector system, erythrocye gene therapy; velurevel; vemurafen- verdis; verteporfin; vinorelbine; vinulsilene; vitoxin; voro- zole; zonotere; zeniplatil; zilascorb; and zincostat sti- malmer. Preferred additional anti-cancer drugs are 5-flu-}

orouracil and leucovorin. These two agents are particularly useful when used in methods employing thalidomide and a topoisomerase inhibitor.

In more particular embodiments, the present invention also comprises the administration of the RNA molecules of the present invention in combination with the administration of one or more therapies such as, but not limited to anti- cancer agents such as those disclosed in Table 1, preferably for the treatment of liver cancers.

The invention also encompasses administration of the RNA molecules of the present invention in combination with radiation therapy comprising the use of x-rays, gamma rays and other sources of radiation to destroy the cancer cells. In preferred embodiments, the radiation treatment is administered as external beam radiation or teletherapy wherein the radiation is directed from a remote source. In other preferred embodiments, the radiation treatment is administered as internal therapy or brachytherapy wherein a radioactively source is placed inside the body close to cancer cells or a tumor mass.

Cancer therapies and their dosages, routes of administration and recommended usage are known in the art and have been described in such literature as the *Physician's Desk Reference* (56th ed., 2002).

5.5. Characterization and Demonstration of Therapeutic or Prophylactic Utility

Toxicity and efficacy of the prophylactic and/or therapeutic protocols of the instant invention can be determined by standard pharmaceutical procedures in cell cultures or experimental animals, e.g., for determining the LD₅₀ (the dose lethal to 50% of the population) and the ED₅₀ (the dose therapeutically effective in 50% of the population). The dose ratio between toxic and therapeutic effects is the therapeutic index and it can be expressed as the ratio LD₅₀/ED₅₀. Prophylactic and/or therapeutic agents that exhibit large therapeutic indices are preferred. While prophylactic and/or therapeutic agents that exhibit toxic side effects may be used, care should be taken to design a delivery system that targets such agents to the site of affected tissue in order to minimize potential damage to uninfected cells and, thereby, reduce side effects.

The data obtained from the cell culture assays and animal studies can be used in formulating a range of dosage of the prophylactic and/or therapeutic agents for use in humans. The dosage of such agents lies preferably within a range of circulating concentrations that include the ED₅₀, with little or no toxicity. The dosage may vary within this range depending upon the dosage form employed and the route of administration utilized. For any agent used in the method of the invention, the therapeutically effective dose can be estimated initially from cell culture assays. A dose may be formulated in animal models to achieve a circulating plasma concentration range that includes the IC₅₀ (i.e., the concentration of the test compound that achieves a half-maximal inhibition of symptoms) as determined in cell culture. Such information can be used to more accurately determine useful doses in humans. Levels in plasma may be measured, for example, by high performance liquid chromatography.

5.6. Demonstration of Therapeutic Utility

The protocols and compositions of the invention are preferably tested in vitro, and then in vivo, for the desired therapeutic or prophylactic activity, prior to use in humans. For example, in vitro assays which can be used to determine whether administration of a specific therapeutic protocol is indicated, include in vitro cell culture assays in which a patient tissue sample is grown in culture, and exposed to or otherwise administered a protocol, and the effect of such protocol upon the tissue sample is observed. A lower level of proliferation or survival of the contacted cells indicates that the therapeutic agent is effective to treat the condition in the patient. Alternatively, instead of culturing cells from a patient, therapeutic agents and methods may be screened using cells of a tumor or malignant cell line or an endothelial cell line. Many assays standard in the art can be used to assess such survival and/or growth; for example, cell proliferation can be assayed by measuring [*H*-thymidine incorporation, by direct cell count, by detecting changes in transcriptional activity of known genes such as proto-oncogenes (e.g., fos, myc) or cell cycle markers; cell viability can be assessed by trypan blue staining, differentiation can be assessed visually based on changes in morphology, etc.

Compounds for use in therapy can be tested in suitable animal model systems prior to testing in humans, including but not limited to in rats, mice, chicken, cows, monkeys, rabbits, hamsters, etc.

The principle animal models for known in the art and widely used are known and described in the art as described above.

Further, any assays known to those skilled in the art can be used to evaluate the prophylactic and/or therapeutic utility of the combinatorial therapies disclosed herein for treatment or prevention of cancer.

5.7. Pharmaceutical Compositions

The compositions of the invention include bulk drug compositions useful in the manufacture of pharmaceutical compositions (e.g., impure or non-sterile compositions) and pharmaceutical compositions (i.e., compositions that are
suitable for administration to a subject or patient) which can be used in the preparation of unit dosage forms. Such compositions comprise a prophylactically or therapeutically effective amount of a prophylactic and/or therapeutic agent disclosed herein or a combination of those agents and a pharmaceutically acceptable carrier. Preferably, compositions of the invention comprise a prophylactically or therapeutically effective amount of RNA molecules of the present invention and/or an anti-cancer agent, and a pharmaceutically acceptable carrier.

In a specific embodiment, the term "pharmaceutically acceptable" means approved by a regulatory agency of the Federal or a state government or listed in the U.S. Pharmacopeia or otherwise generally recognized pharmacopeia for use in animals, and more particularly in humans. The term "carrier" refers to a diluent, adjuvant (e.g., Freund's adjuvant (complete and incomplete)), excipient, or vehicle with which the therapeutic is administered. Such pharmaceutical carriers can be sterile liquids, such as water and oils, including those of petroleum, animal, vegetable or synthetic origin, such as peanut oil, soybean oil, mineral oil, sesame oil and the like. Water is a preferred carrier when the pharmaceutical composition is administered intravenously. Saline solutions and aqueous dextrose and glycercol solutions can also be employed as liquid carriers, particularly for injectable solutions. Suitable pharmaceutical excipients include starch, glucose, lactose, sucrose, gelatin, malt, rice, flour, chalk, silica gel, sodium stearate, glycerol monostearate, talc, sodium chloride, dried skim milk, glycerol, propylene glycol, water, ethanol and the like. The composition, if desired, may also contain minor amounts of wetting or emulsifying agents, or pH buffering agents. These compositions can take the form of solutions, suspensions, emulsions, tablets, pills, capsules, powders, sustained-release formulations and the like.

Generally, the ingredients of compositions of the invention are supplied either separately or mixed together in unit dosage form, for example, as a dry lyophilized powder or water free concentrate in a hermetically sealed container such as an ampoule or sachette indicating the quantity of active agent. Where the composition is to be administered by infusion, it can be dispensed with an infusion bottle containing sterile pharmaceutical grade water or saline. Where the composition is administered by injection, an ampoule of sterile water for injection or saline can be provided so that the ingredients may be mixed prior to administration.

The compositions of the invention can be formulated as neutral or salt forms. Pharmaceutically acceptable salts include those formed with anions such as those derived from hydrochloric, phosphoric, acetic, oxalic, tartaric acids, etc., and those formed with cations such as those derived from sodium, potassium, ammonium, calcium, ferric hydroxides, isopropylamine, triethylamine, 2-ethylamino ethanol, histidine, procaine, etc.

Various delivery systems are known and can be used to administer the RNA molecules of the present invention or the combination of the RNA molecules of the present invention and a prophylactic agent or therapeutic agent useful for preventing or treating cancer, e.g., encapsulation in liposomes, microspheres, microcapsules, recombinant cells capable of expressing the antibody or antibody fragment, receptor-mediated endocytosis (see, e.g., Wu and Wu, J. Biol. Chem. 262:4429-4432 (1987)), construction of a nucleic acid as part of a retroviral or other vector, etc.

Methods of administering a prophylactic or therapeutic agent of the invention include, but are not limited to, parenteral administration (e.g., intradermal, intramuscular, intraperitoneal, intravenous and subcutaneous), epidural, and mucosal (e.g., intranasal and oral routes). In a specific embodiment, prophylactic or therapeutic agents of the invention are administered intramuscularly, intravenously, or subcutaneously. The prophylactic or therapeutic agents may be administered by any convenient route, for example by infusion or bolus injection, by absorption through epithelial or mucocutaneous linings (e.g., oral mucosa, rectal and intestinal mucosa, etc.) and may be administered together with other biologically active agents. Administration can be systemic or local.

In a specific embodiment, it may be desirable to administer the prophylactic or therapeutic agents of the invention locally to the area in need of treatment; this may be achieved by, for example, and not by way of limitation, local infusion, by injection, or by means of an implant, said implant being of a porous, non-porous, or gelatinous material, including membranes, such as sialastic membranes, or fibers.

In yet another embodiment, the prophylactic or therapeutic agent can be delivered in a controlled release or sustained release system. In one embodiment, a pump may be used to achieve controlled or sustained release (see Langer, supra; Selkon, 1987, CRC Crit. Rev. Biomed. Eng. 14:20; Buchwald et al., 1980, Surgery 88:597; Sandell et al., 1989, N. Engl. J. Med. 321:574). In another embodiment, polymeric materials can be used to achieve controlled or sustained release of the antibodies of the invention or fragments thereof (see, e.g., Medical Applications of Controlled Release, Langer and Wise (eds.), CRC Press, Boca Raton, Fla. (1974); Controlled Drug Bioavailability, Drug Product Design and Performance, Smolen and Ball (eds.), Wiley, New York (1984); and Ranger and Peppas, 1983, J. Macromol. Sci. Rev. Macromol. Chem. 23:61; see also Levy et al., 1985, Science 228:190; Drying et al., 1989, Ann. Neurol. 25:351; Howard et al., 1989, J. Neurosurg. 71:1055; U.S. Pat. Nos. 5,679,377; 5,916,597; 5,912,015; 5,989,463; 5,128,326; PCT Publication No. WO 99/15154; and PCT Publication No. WO 99/20253. Examples of polymers used in sustained release formulations include, but are not limited to, poly(2-hydroxy ethyl methacrylate), poly(methyl methacrylate), poly(acrylic acid), poly(ethylene-co-vinyl acetate), poly(methacrylic acid), polyglycolides (PLG), polyanhydrides, poly(N-vinyl pyrrolidone), poly(vinyl alcohol), polyacrylamide, poly(ethylene glycol), polylactides (PLA), poly(lactide-co-glycolides) (PLGA), and polylactoesters. In a preferred embodiment, the polymer used in a sustained release formulation is inert, free of leachable impurities, stable on storage, sterile, and bioabsorbable.

In yet another embodiment, a controlled or sustained release system can be placed in proximity of the prophylactic or therapeutic target, thus requiring only a fraction of the systemic dose (see, e.g., Goodson, in Medical Applications of Controlled Release, supra, vol. 2, pp. 115-138 (1984)).

5 5.7.1. Formulations

Pharmaceutical compositions for use in accordance with the present invention may be formulated in conventional manner using one or more pharmaceutically acceptable carriers or excipients.

Thus, the RNA molecules of the present invention or other anti-cancer agents and their physiologically acceptable salts and solvents may be formulated for administration by infusion or insufflation (either through the mouth or the nose) or oral, parenteral or mucosal (such as buccal, vaginal, rectal, sublingual) administration. In a preferred embodiment, local or systemic parenteral administration is used.

For oral administration, the pharmaceutical compositions may take the form of, for example, tablets or capsules prepared by conventional means with pharmaceutically acceptable excipients such as binding agents (e.g., pregelatinised maize starch, polyvinylpyrrolidone or hydroxypropyl methylcellulose); fillers (e.g., lactose, microcrystalline cellulose or calcium hydrogen phosphate); lubricants (e.g., magnesium stearate, talc or silica); disintegrants (e.g., potato starch or sodium starch glycinate); or wetting agents (e.g., sodium lauryl sulphate). The tablets may be coated by methods well known in the art. Liquid preparations for oral administration may take the form of, for example, solutions, syrups or suspensions, or they may be presented as a dry product for constitution with water or other suitable vehicle before use. Such liquid preparations may be prepared by conventional means with pharmaceutically acceptable additives such as suspending agents (e.g., sorbitol syrup, cellulose derivatives or hydroxyethyl cellulose); emulsifying agents (e.g., lecithin or acacia); non-aqueous vehicles (e.g., almond oil, oily esters, ethyl alcohol or fractionated vegetable oils); and preservatives (e.g., methyl or propyl-p-hydroxybenzoates or sorbic acid). The preparations may also contain buffer salts, flavoring, coloring and sweetening agents as appropriate.

Preparations for oral administration may be suitably formulated to give controlled release of the active compound.

For buccal administration the compositions may take the form of tablets or lozenges formulated in conventional manner.

For administration by inhalation, the prophylactic or therapeutic agents for use according to the present invention are conveniently delivered in the form of an aerosol spray presentation from pressurized packs or a nebuliser, with the use of a suitable propellant, e.g., dichlorodifluoromethane, trichlorofluoromethane, dichlorotetrafluoroethane, carbon dioxide or other suitable gas. In the case of a pressurized aerosol the dosage unit may be determined by providing a valve to deliver a metered amount. Capsules and cartridges of e.g., gelatin for use in an inhaler or insufflator may be formulated containing a powder mix of the compound and a suitable powder base such as lactose or starch.

The prophylactic or therapeutic agents may be formulated for parenteral administration by injection, e.g., by bolus injection or continuous infusion. Formulations for injection may be presented in unit dosage form, e.g., in ampoules or in multi-dose containers, with an added preservative. The compositions may take such forms as suspensions, solutions or emulsions in oily or aqueous vehicles, and may contain formulated agents such as suspending, stabilizing and/or dispersing agents. Alternatively, the active ingredient may be in powder form for constitution with a suitable vehicle, e.g., sterile pyrogen-free water, before use.

The prophylactic or therapeutic agents may also be formulated in rectal compositions such as suppositories or retention enemas, e.g., containing conventional suppository bases such as cocoa butter or other glycerides.

In addition to the formulations described previously, the prophylactic or therapeutic agents may also be formulated as a depot preparation. Such long acting formulations may be administered by implantation (for example subcutaneously or intramuscularly) or by intramuscular injection. Thus, for example, the prophylactic or therapeutic agents may be formulated with suitable polymeric or hydrophobic materials (for example as an emulsion in an acceptable oil) or ion exchange resins, or as sparingly soluble derivatives, for example, as a sparingly soluble salt.

The invention also provides that a prophylactic or therapeutic agent is packaged in a hermetically sealed container such as an ampoule or sachette indicating the quantity. In one embodiment, the prophylactic or therapeutic agent is supplied as a dry sterilized lyophilized powder or water free concentrate in a hermetically sealed container and can be reconstituted, e.g., with water or saline to the appropriate concentration for administration to a subject.

In a preferred embodiment of the invention, the formulation and administration of various chemotherapeutic, biological/immunotherapeutic and hormonal therapeutic agents are known in the art and often described in the Physician’s Desk Reference, 56th ed. (2002). For instance, in certain specific embodiments of the invention, the therapeutic agents of the invention can be formulated and supplied as provided in Table 1.

In other embodiments of the invention, radiation therapy agents such as radioactive isotopes can be given orally as liquids in capsules or as a drink. Radioactive isotopes can also be formulated for intravenous injections. The skilled oncologist can determine the preferred formulation and route of administration.

The compositions may, if desired, be presented in a pack or dispenser device that may contain one or more unit dosage forms containing the active ingredient. The pack may for example comprise metal or plastic foil, such as a blister pack. The pack or dispenser device may be accompanied by instructions for administration.

In certain preferred embodiments, the pack or dispenser contains one or more unit dosage forms containing no more than the recommended dosage formulation as determined in the Physician’s Desk Reference (56th ed. 2002), herein incorporated by reference in its entirety for a particular cancer therapy.

5.7.2. Dosages

The amount of the composition of the invention which will be effective in the treatment, prevention or management of diseases related to HBV including, but not limited to, cancer, can be determined by standard research techniques. For example, the dosage of the composition which will be effective in the treatment, prevention or management of a disease can be determined by administering the composition to an animal model such as, e.g., the animal models disclosed herein or known to those skilled in the art. In addition, in vitro assays may optionally be employed to help identify optimal dosage ranges.

Selection of the preferred effective dose can be determined (e.g., via clinical trials) by a skilled artisan based upon the consideration of several factors which will be known to one of ordinary skill in the art. Such factors include the disease to be treated or prevented, the symptoms
involved, the patient’s body mass, the patient’s immune status and other factors known by the skilled artisan to reflect the accuracy of administered pharmaceutical compositions.

The precise dose to be employed in the formulation will also depend on the route of administration, and the seriousness of the cancer, and should be decided according to the judgment of the practitioner and each patient’s circumstances. Effective doses may be extrapolated from dose-response curves derived from in vitro or animal model test systems.

For antibodies, the dosage administered to a patient is typically 0.1 mg/kg to 100 mg/kg of the patient’s body weight. Preferably, the dosage administered to a patient is between 0.1 mg/kg and 20 mg/kg of the patient’s body weight, more preferably 1 mg/kg to 10 mg/kg of the patient’s body weight. Generally, human and humanized antibodies have a longer half-life within the human body than antibodies from other species due to the immune response to the foreign polypeptides. Thus, lower dosages of human antibodies and less frequent administration is often possible.

For other cancer therapeutic agents administered to a patient, the typical dosages of various cancer therapeutics known in the art are provided in Table 1. Given the invention, certain preferred embodiments will encompass the administration of lower dosages in combination treatment regimens than dosages recommended for the administration of single agents.

The invention provides for any method of administering lower doses of known prophylactic or therapeutic agents than previously thought to be effective for the prevention, treatment, management or amelioration of cancer. Preferably, lower doses of known anti-cancer therapies are administered in combination with lower doses of the RNA molecule of the present invention.

5.8. Kits

The invention provides a pharmaceutical pack or kit comprising one or more containers filled with the RNA molecules of the present invention and one or more prophylactic or therapeutic agents useful for the treatment of cancer. The invention also provides a pharmaceutical pack or kit comprising one or more containers filled with one or more of the ingredients of the pharmaceutical compositions of the invention. Optionally associated with such container(s) can be a notice in the form prescribed by a governmental agency regulating the manufacture, use or sale of pharmaceuticals or biological products, which notice reflects approval by the agency of manufacture, use or sale for human administration.

The present invention provides kits that can be used in the above methods. In one embodiment, a kit comprises the RNA molecules of the present invention, in one or more containers, and one or more other prophylactic or therapeutic agents useful for the treatment of cancer, in one or more containers. In certain preferred embodiments, the other prophylactic or therapeutic agent is a chemotherapeutic. In certain preferred embodiments, the prophylactic or therapeutic agent is a biological or hormonal therapeutic. In certain preferred embodiments, the other prophylactic or therapeutic agent is a biological or hormonal therapeutic.

5.9. Gene Therapy

Gene therapy refers to treatment or prevention methods performed by the administration of a nucleic acid to a subject. In this embodiment of the invention, the therapeutic nucleic acid produces intracellularly a RNA molecule of the present invention that mediates a therapeutic effect by inhibiting gene expression. In another embodiment, nucleic acids comprising a sequence encoding the RNA molecules of the present invention are administered to inhibit HBV gene in the cell.

Delivery of the nucleic acid into a patient may be either direct, in which case the patient is directly exposed to the nucleic acid or nucleic acid-carrying vector or a delivery complex, or indirect, in which case, cells are first transformed with the nucleic acid in vitro, then transplanted into the patient. These two approaches are known, respectively, as in vivo or ex vivo gene therapy.

In a specific embodiment, the nucleic acid is directly administered in vivo, where it is expressed to produce the RNA molecules of the present invention. This can be accomplished by any of numerous methods known in the art, e.g., by constructing it as part of an appropriate nucleic acid expression vector and administering it so that it becomes intracellular, e.g., by infection using a defective or attenuated retroviral or other viral vector (see U.S. Pat. No. 4,980,286), or by direct injection, or by use of microparticle bombardment (e.g., a gene gun; Biologic, Dupont), or coating with lipids or cell-surface receptors or transfecting agents, encapsulation in biopolymers (e.g., see U.S. Pat. No. 5,635,493), encapsulation in liposomes, microparticles, or microcapsules, or by administering it in linkage to a peptide which is known to enter the nucleus, by administering it in linkage to a ligand subject to receptor-mediated endocytosis (see e.g., Wu and Wu, 1987, J. Biol. Chem. 262:4429-4432), etc. In another embodiment, a nucleic acid-ligand complex can be formed in which the ligand comprises a fusogenic viral peptide to disrupt endosomes, allowing the nucleic acid to avoid lysosomal degradation. In yet another embodiment, the nucleic acid can be targeted in vivo for cell specific uptake and expression, by targeting a specific receptor (see, e.g., PCT Publications WO 92/06180 dated Apr. 16, 1992 (Wu et al.); WO 92/22635 dated Dec. 23, 1992 (Wilson et al.); WO92/20316 dated Nov. 26, 1992 (Findelis et al.); WO93/14188 dated Jul. 22, 1993 (Clarke et al.); WO 93/20221 dated Oct. 14, 1993 (Young)). Alternatively, the nucleic acid can be introduced intracellularly and incorporated within host cell DNA for expression, by homologous recombination (Koller and Smithies, 1989, Proc. Natl. Acad. Sci. USA 86:8932-8935; Zijlstra et al., 1989, Nature 342: 435-438).

In a specific embodiment, a viral vector that expresses the RNA molecules of the present invention is used. For
example, a retroviral vector can be used (see Miller et al., 1993, Meth. Enzymol. 217:581–599). These retroviral vectors have been modified to create retroviral sequences that are not necessary for packaging of the viral genome and integration into host cell DNA. The RNA molecules of the present invention to be used in gene therapy is cloned into the vector, which facilitates delivery of the gene into a patient. More detail about retroviral vectors can be found in Boesen et al., 1994, Biotherapy 6:291–302, which describes the use of a retroviral vector to deliver the mdr1 gene to hematopoietic stem cells in order to make the stem cells more resistant to chemotherapy. Other references illustrating the use of retroviral vectors in gene therapy arc: Clowes et al., 1994, J. Clin. Invest. 93:644–651; Kiern et al., 1994, Blood 83:1467–1473; Salmons and Gunzburg, 1993, Human Gene Therapy 4:129–141; and Grossman and Wilson, 1993, Curr. Opin. in Genetics and Devel. 3:110–114.

Adenoviruses are other viral vectors that can be used in gene therapy. Adenoviruses are especially attractive vectors for delivering genes to respiratory epithelia. Adenoviruses naturally infect respiratory epithelia where they cause a mild disease. Other targets for adenovirus-based delivery systems are liver, the central nervous system, endothelial cells, and muscle. Adenoviruses have the advantage of being capable of infecting non-dividing cells. Kozarsky and Wilson, 1993, Current Opinion in Genetics and Development 3:499–503 present a review of adenovirus-based gene therapy. Bout et al., 1994, Human Gene Therapy 5:3–10 demonstrated the use of adenovirus vectors to transfer genes to the respiratory epithelia of rhesus monkeys. Other instances of the use of adenoviruses in gene therapy can be found in Rosenfeld et al., 1991, Science 252:431–434; Rosenfeld et al., 1992, Cell 68:143–155; and Masri and Behr, 1993, J. Clin. Invest. 91:225–234.

Adeno-associated virus (AAV) has also been proposed for use in gene therapy (Walsh et al., 1993, Proc. Soc. Exp. Biol. Med. 204:289–300. Numerous techniques are known in the art for the introduction of foreign genes into cells (see e.g., Loefler and Beltr, 1993, Meth. Enzymol. 217:599–618; Cohen et al., 1993, Meth. Enzymol. 217:618–644; Clain, 1985, Pharmac. Ther. 29:69–92). The technique should provide for the stable transfer of the nucleic acid to the cell, so that the nucleic acid is expressible by the cell and preferably heritable and expressible by its cell progeny.

The resulting recombinant cells can be delivered to a patient by various methods known in the art. In a preferred embodiment, recombinant blood cells (e.g., hematopoietic stem or progenitor cells) are preferably administered intravenously.

6. EXAMPLES

Constructs

pAU6*27, which contains human U6 promoter and the first 27-bp of U6 RNA coding sequence, has been described by Paul et al., 2002, Nat Biotechnol 20:505–508. A series of shRNA expression vectors was generated by inserting annealed oligos containing sense-TCGG-antisense sequence into pAU6*27 vector between Sal I and Xba I sites. The oligo sequences for the sense strand of shRNA were:

Cell Culture, Transfection, and Reporter Gene Assays

HepG2 cells were grown in DMEM with 10% fetal bovine serum in 10-cm dishes. Transfections were carried out using Lipofectamine 2000 reagent (Invitrogen, MD) as described in the manufacturer’s instructions. The transfected cells were selected with 500 μg/ml of G418 for three weeks with medium change every three days. The cells for the stable expression of shRNA were used for HBV replication assay.

To detect the effects of stably-expressed shRNA on HBV RNA degradation and replication, HepG2 cells were cotransfected with 100 ng of luciferase expression plasmid pMD1948 (He et al., 1999, Proc Natl Acad Sci USA 96:10212–10217) and 900 ng of pHBV (Fu et al., 1998, Biochem Pharmacol 55:1567–1572; Fu et al., 1997, Chin J. Virol., 13:215-223) in each well of 12-well plates. Luciferase activities were determined after 72 hrs using a luciferase detection kit (Promega, Wis.). The HBV titers were normalized by luciferase activities. To test the synergistic effects of shRNA and lamivudine (3TC), the shRNA stable-expression cells cotransfected with pHBV and pMD1948 were culture in 3TC containing medium (0.5 μM) and harvested after 6-day incubation with fresh medium change every two days.

Quantitative PCR Analysis

Real-time PCR was performed to quantify HBV viral genomic DNA or mRNA using an HBV diagnostic kit (PG Biotech. Ltd., Shenzhen, China) described previously. He et al., 2002, Biochim Biophys Res Commun 295:1102–1107. For measurement of viral genomic DNA, HepG2 cells were harvested 72 hrs post-transfection and lysed in 200 μl of lysis buffer (PBS with 1% NP-40 and cocktail protein inhibitors). The luciferase activities were determined using 25 μl of cell lysates. The remaining cell lysates were treated with DNase 1 (final conc. 1 mg/ml) at
37°C. for 60 min to remove the transfected plasmid DNA before the isolation of HBV genomic DNA from core particles. To quantify the mRNA of HBV, the total mRNA was isolated using Trizol reagent (Invitrogen, MD) and reverse-transcribed (RT) to cDNA using oligo dT priming. Quantitative RT-PCR experiments were carried out and the values were normalized with luciferase mRNA (internal control). To quantify luciferase mRNA (internal control), primer 5'-GGAGAACCACCGCTTACTGG CAA-3' (Luc_F) (SEQ ID NO:11), 5'-GCCGGCAGACG ATGAAAGAAATG-3' (Luc_R) (SEQ ID NO:12) and probe 5'-FAM ATGCCATGGCTACATTCTTGGA GACATAG-TAMRA-3' (SEQ ID NO:13) were used in the real-time PCR reactions.

7. Equivalents

Those skilled in the art will recognize, or be able to ascertain many equivalents to the specific embodiments of the invention described herein using no more than routine experimentation. Such equivalents are intended to be encompassed by the following claims.

All publications, patents and patent applications mentioned in this specification are herein incorporated by reference into the specification to the same extent as if each individual publication, patent or patent application was specifically and individually indicated to be incorporated herein by reference.

Citation or discussion of a reference herein shall not be construed as an admission that such is prior art to the present invention.

What is claimed is:

1. An isolated nucleic acid molecule comprising the nucleotide sequence of SEQ ID NO:1, 2, 3, 4, 7, or 10, or a complement thereof.
2. The nucleic acid molecule of claim 1 wherein said nucleic acid molecule is double-stranded.
3. The nucleic acid molecule of claim 2 wherein said nucleic acid molecule is a RNA.
4. A vector comprising the nucleic acid molecule of claim 1.
5. The vector of claim 4, wherein said nucleic acid molecule is operatively linked to a human U6 promoter.

6. The vector of claim 4, wherein said nucleic acid molecule comprises a sense-TCG-antisense sequence of said nucleotide sequence.
7. The isolated nucleic acid molecule of claim 1, wherein said nucleic acid molecule comprises a sense-TCG-antisense sequence of said nucleotide sequence.
8. The nucleic acid molecule of claim 7, wherein said nucleic acid molecule is a RNA.
