I. INTRODUCTION

The nature of the scalar mesons \(a_0(980)\) and \(f_0(980)\) has been a hot topic in light hadron physics for many years. These two states, with similar masses but different decay modes, are difficult to accommodate in the constituent quark-antiquark scenario. Tremendous efforts in both experiment and theory have been made in order to understand them. Suggestions for their being exotic candidates, such as tetraquark states, hybrids, or \(K\bar{K}\) molecules, can be found in the literature [1–6].

The possibility of mixing between \(a_0(980)\) and \(f_0(980)\) was suggested long ago, and its measurement will shed light on the nature of these two resonances [7–14]. In particular, the leading contribution to the isospin-violating mixing transition amplitudes for \(f_0(980) \rightarrow a_0(980)\) and \(a_0(980) \rightarrow f_0(980)\) is shown to be dominated by the difference of the unitarity cut which arises from the mass difference between the charged and neutral \(K\bar{K}\) pairs. As a consequence, a narrow peak of about 8 MeV/\(c^2\) is predicted between the charged and neutral \(K\bar{K}\) thresholds [8,13,14].

The mixing amplitudes strongly depend on the couplings of \(a_0(980)\) and \(f_0(980)\) to \(K\bar{K}\), and to probe the properties of these two scalar states, precise measurements of the mixing transitions are very important. Two kinds of mixing intensities, i.e., \(\xi_{fa}\) and \(\xi_{af}\) for the \(f_0(980) \rightarrow a_0(980)\) and \(a_0(980) \rightarrow f_0(980)\) transitions, respectively, can be defined and are accessible to measurement in charmonium decays [13,14]:

\[
\xi_{fa} = \frac{\text{Br}(J/\psi \rightarrow \phi f_0(980) \rightarrow \phi a_0(980) \rightarrow \phi \eta \pi^0)}{\text{Br}(J/\psi \rightarrow \phi f_0(980) \rightarrow \phi \pi \pi)}
\]

and

\[
\xi_{af} = \frac{\text{Br}(\chi_{c1} \rightarrow \pi^0 a_0(980) \rightarrow \pi^0 f_0(980) \rightarrow \pi^0 \pi^+ \pi^-)}{\text{Br}(\chi_{c1} \rightarrow \pi^0 a_0(980) \rightarrow \pi^0 \pi^0 \eta)}.
\]
Using samples of $2.25 \times 10^6 J/\psi$ events [15] and $1.06 \times 10^6 \psi'$ events [16] collected with the BES III detector in 2009, we perform direct measurements of the $\alpha_0^J(980) - f_0(980)$ mixing intensities via the processes $J/\psi \to \phi f_0(980) \to \phi \alpha_0^J(980) \to \phi \eta \pi^0$ and $\chi_{c1} \to \pi^0 \alpha_0^J(980) \to \pi^0 f_0(980) \to \pi^0 \pi^+ \pi^-$. 

II. DETECTOR AND MONTE CARLO SIMULATION

BEPC II is a double-ring $e^+e^-$ collider designed to provide a peak luminosity of $10^{33}$ cm$^{-2}$s$^{-1}$ at a beam current of 0.93 A. The BES III detector has a geometrical acceptance of 93% of 4π and has four main components:

1. A small-cell, helium-based (40% He, 60% C$_3$H$_6$) main drift chamber with 43 layers providing an average single-hit resolution of 15 μm, charged-particle momentum resolution in a 1 T magnetic field of 0.5% at 1 GeV/c, and the $de/dx$ resolution that is better than 6%. (2) An electromagnetic calorimeter (EMC) consisting of 6240 CsI (TI) crystals in a cylindrical structure (barrel) and two end caps. The energy resolution at 1.0 GeV/c is 2.5% (5%) in the barrel (end caps), and the position resolution is 6 mm (9 mm) in the barrel (end caps). (3) A time-of-flight system constructed of 5-cm-thick plastic scintillators, with 176 detectors of 2.4 m length in two layers in the barrel and 96 fan-shaped detectors in the end caps. The barrel (end cap) time resolution of 80 ps (110 ps) provides $2\sigma K/\pi$ separation for momenta up to $\sim 1.0$ GeV/c. (4) The muon system consists of 1000 m$^2$ of resistive plate chambers in nine barrel and eight end cap layers and provides 2 cm position resolution.

The efficiency for $J/\psi \to \phi f_0(980) \to \phi \alpha_0^J(980) \to \phi \eta \pi^0$ is estimated using a Monte Carlo (MC) simulation of $J/\psi \to \phi S$, where $S$ is the mixing signal represented by a narrow scalar Breit-Wigner uniformly decaying to $\eta \pi^0$. The mass of the mixing signal is set to be 991.3 MeV/c$^2$ [the center of $(m_{K^+} + m_{K^-})$ and $(m_{K^0} + m_{\bar{K}^0})$ [17]], and the width of the mixing signal is set to be 8 MeV/c$^2$. The efficiency for $\psi' \to \gamma \chi_{c1} \to \gamma \pi^0 \alpha_0^J(980) \to \gamma \pi^0 f_0(980) \to \gamma \pi^0 \pi^+ \pi^-$ is estimated using a Monte Carlo simulation of $\psi' \to \gamma \chi_{c1} \to \gamma \pi^0 S$, where $S$ is the mixing signal with parameters as above, and decays into $\pi^+ \pi^-$ isotropically.

III. EVENT SELECTION

Tracks of charged particles in BES III are reconstructed from main drift chamber hits. We select tracks within ±20 cm of the interaction point in the beam direction and within 2 cm in the plane perpendicular to the beam. The time-of-flight and $de/dx$ information are combined to form particle identification (PID) confidence levels for the $\pi$, $K$, and $p$ hypotheses; each track is assigned to the particle type that corresponds to the hypothesis with the highest confidence level.

IV. MEASUREMENT OF $J/\psi \to \phi f_0(980) \to \phi \alpha_0^J(980) \to \phi \eta \pi^0$

Photon candidates are reconstructed by clustering EMC crystal energies. Efficiency and energy resolution are improved by including energy deposits in nearby time-of-flight counters. The minimum energy is 25 MeV for barrel showers (|cosθ| < 0.80) and 50 MeV for end cap showers (0.86 < |cosθ| < 0.92). To exclude showers from charged particles, the angle between the nearest charged track and the shower must be greater than 10°. EMC cluster timing requirements suppress electronic noise and energy deposits unrelated to the event.

The $\pi^0 \to \gamma \gamma$ and $\eta \to \gamma \gamma$ candidates are formed from pairs of photon candidates that are kinematically fit to the known resonance masses, and the $\chi^2$ from the kinematic fit with 1 degree of freedom is required to be less than 25. The decay angle of a photon is the polar angle measured in the $\eta$ or $\pi^0$ rest frame with respect to the $\eta$ or $\pi^0$ direction in the $J/\psi$ or $\psi'$ rest frame. Real $\eta$ and $\pi^0$ mesons decay isotropically, and their angular distributions are flat. However, the $\eta$ and $\pi^0$ candidates which originate from a wrong photon combination do not have a flat distribution in this variable. To remove wrong photon combinations, the decay angle is required to satisfy $|\cos\theta_{\text{decay}}| < 0.95$.

Figure 1(b) shows the $\eta \pi^0$ invariant mass distribution recoiling against the $\phi$ signal (|$m_{K^+K^-} - 1.02| < 0.015$ GeV/c$^2$). A narrow structure appears around 980 MeV/c$^2$. The shaded histogram shows the $\eta \pi^0$ invariant mass of events recoiling against the $\phi$ sideband (1.065 GeV/c$^2 < m_{K^+K^-} < 1.095$ GeV/c$^2$), and no sign of a peak near 980 MeV/c$^2$ is evident. Exclusive MC samples of $J/\psi$ decays which have similar final states are generated to check whether a peak near 980 MeV/c$^2$ can be produced in the $\eta \pi^0$ mass spectrum. The main backgrounds come from: (1) $J/\psi \to \phi \pi^0 \pi^0$ via $f_0(980)$, $f_2(1270)$, or a phase space process; and (2) $J/\psi \to K^*K \eta$ + c.c., $J/\psi \to K_2^*(1430)K \eta$ + c.c., and $J/\psi \to \gamma f_{21}(1590) \to \gamma K^*K^*$. The $\eta \pi^0$ invariant mass distribution from all these possible background sources is shown in Fig. 1(a), where a clear peak near 980 MeV/c$^2$ is evident.
Crystal Barrel experiment results in Ref. [13,19]. The coupling constants and mass as used here are taken from the M. ABLIKIM et al. MC sample. In the mass distributions of events selected from the inclusive J = 0 

\[ \phi \rightarrow K^+ K^- \eta \pi^0 \] 

The solid arrows show the \( \phi \) mass window. The dashed arrows show the \( \phi \) sideband region used to estimate backgrounds. The \( \eta \pi^0 \) invariant mass of selected events is shown in (b)–(d). The dots with error bars show the mass spectrum of \( M_{\eta \pi^0} \) recoiling against the \( \phi \). The shaded histogram is (b) recoiling against the \( \phi \) sideband; (c) from exclusive MC; and (d) from inclusive MC.

![Fig. 1](https://example.com/figure1.png)

**FIG. 1** (color online). (a) The invariant mass spectrum of \( K^+ K^- \) in \( J/\psi \rightarrow K^+ K^- \eta \pi^0 \). The solid arrows show the \( \phi \) mass window. The dashed arrows show the \( \phi \) sideband region used to estimate backgrounds. The \( \eta \pi^0 \) invariant mass of selected events is shown in (b)–(d). The dots with error bars show the mass spectrum of \( M_{\eta \pi^0} \) recoiling against the \( \phi \). The shaded histogram is (b) recoiling against the \( \phi \) sideband; (c) from exclusive MC; and (d) from inclusive MC.

Channels is smooth, shown as the shaded region in Fig. 1(c), and will not affect the determination of the number of mixing events.

A MC sample of \( 2.0 \times 10^8 \) inclusive \( J/\psi \) decay events is used to investigate other possible backgrounds too. The shaded histogram in Fig. 1(d) shows the \( \eta \pi^0 \) invariant mass distributions of events selected from the inclusive MC sample. In the 980 MeV/c^2 region, there is no peaking background.

An underlying process is from \( J/\psi \rightarrow \phi a_0^0(980) \) via a \( \gamma^* \) or \( K^* K \) loops [13]. However, it will produce a much broader distribution (50–100 MeV/c^2) in the \( \eta \pi^0 \) mass spectrum than \( f_0(980) \rightarrow a_0^0(980) \) mixing [13]. We estimate its contribution in the fit to the mass spectrum.

A simultaneous unbinned maximum likelihood fit to the \( \eta \pi^0 \) mass spectrums recoiling against the \( \phi \) and the \( \phi \) sideband is performed. In the signal region, the probability density function is composed of the mixing signal, represented by the shape extracted from MC simulation of a narrow Breit-Wigner, the \( a_0^0(980) \) contribution from \( \gamma^* \) or \( K^* K \) loops represented by a Flatté formula, and a 2nd order polynomial for the backgrounds. In the sideband region, the probability density function is a 2nd order polynomial only. The mass of the mixing signal is set to 991.3 MeV/c^2 [the center of \( (m_{K^+} + m_{K^-}) \) and \( (m_{K^0} + m_{K^0}) \) [17]], and the width of the mixing signal is set to 8 MeV/c^2. The shape parameters of the background polynomials in the signal region and the sideband region are constrained to vary simultaneously in the fit. The normalization of each component is allowed to float. Figures 2(a) and 2(b) show the results of the simultaneous fit.

The fit yields \( N(f_0 \rightarrow a_0^0) = 25.8 \pm 8.6 \) events for the mixing signal and \( N(a_0^0(980)) = 13.6 \pm 24.8 \) events for the \( a_0^0(980) \) contribution from \( \gamma^* \) or \( K^* K \) loops. Comparing with the fit result without the mixing signal, the change in \( -\ln L \) with \( \Delta (\text{d.o.f.}) = 1 \) is 5.90, corresponding to a statistical significance of 3.4\( \sigma \). Comparing with the fit result without the \( a_0^0(980) \) contribution from \( \gamma^* \) or \( K^* K \) loops, the change in \( -\ln L \) with \( \Delta (\text{d.o.f.}) = 1 \) is 0.14, corresponding to a statistical significance of 0.5\( \sigma \). Using the Bayesian method, the upper limit for the number of mixing events is 37.5, and the upper limit of the number of \( a_0^0(980) \) from \( \gamma^* \) or \( K^* K \) loops is 50.8 events at the 90% confidence level (C.L.). The results are listed in Table 1.

The branching ratio of the mixing signal \( J/\psi \rightarrow \phi f_0(980) \rightarrow \phi a_0^0(980) \rightarrow \phi \eta \pi^0 \) is calculated as

---

1The Flatté formula is taken from Ref. [18]. The values of coupling constants and mass as used here are taken from the Crystal Barrel experiment results in Ref. [13,19].
The total branching ratio of $J/\psi \rightarrow \phi \eta \pi^0$ is calculated as

$$\text{Br}(J/\psi \rightarrow \phi \eta \pi^0) = \frac{N(f_0 \rightarrow a_0^0)/\epsilon_f \cdot N_{J/\psi}}{N_{J/\psi} \cdot \text{Br}(\phi \rightarrow K^+ K^\mp) \cdot \text{Br}(\eta \rightarrow \gamma \gamma) \cdot \text{Br}(\pi^0 \rightarrow \gamma \gamma)},$$

where $\epsilon_f = (18.3 \pm 0.2\%)$ is the efficiency for the underlying process $J/\psi \rightarrow \phi a_0^0(980) \rightarrow \phi \eta \pi^0$. The branching ratio is then determined to be $(5.0 \pm 2.7) \times 10^{-6}$, where the error is statistical only.

If we fit the $\eta \pi^0$ invariant mass spectrum only with the mixing signal plus a 2nd order polynomial background, the fit yields $28.6 \pm 7.0$ events for the mixing signal. Comparing with the fit result with only the 2nd order polynomial, the change in $-\ln L$ with $\Delta$(d.o.f.) = 1 is 10.89, corresponding to a statistical significance of 4.7$\sigma$. The upper limit at the 90% C.L. is 99.1 events. The results are listed in Table I. The total branching ratio of $J/\psi \rightarrow \phi a_0^0(980) \rightarrow \phi \eta \pi^0$ is calculated to be $(9.7 \pm 2.2) \times 10^{-6}$, where the error is statistical only.

V. MEASUREMENT OF $\psi' \rightarrow \gamma \chi_{c1} \rightarrow \gamma \pi^0 a_0^0(980) \rightarrow \gamma \pi^0 f_0(980) \rightarrow \gamma \pi^0 \pi^- \pi^-$

Events with two oppositely charged tracks identified as pions and at least three photons, which form at least one distinct $\pi^0$ candidate, are selected. A 5C kinematic fit is performed to the $\psi' \rightarrow \gamma \pi^0 \pi^- \pi^-$ hypothesis (constraints are the 4-momentum of $\psi'$ and the $\pi^0$ mass) and $\chi^2_{5C} < 60$ is required. If there is more than one combination, the

</table>
combination with the smallest $\chi^2_{3C}$ is retained. The events are also fitted to $\psi' \rightarrow \pi^0 \pi^+ \pi^- \pi^-$ and $\psi' \rightarrow \pi^0 \pi^0 \pi^+ \pi^- \pi^-$, and the probabilities are required to be less than that from the kinematic fit to the signal channel $\psi' \rightarrow \gamma \pi^+ \pi^- \pi^0$. To remove background with a $J/\psi$ decaying to leptons, the angle between the two charged tracks is required to be less than 160°. We further require the ratio of energy deposited by each charged track in the EMC to its momentum measured in the main drift chamber to be less than 0.85. To remove backgrounds which have $\gamma \gamma J/\psi$ final states, the mass recoiling from any photon pair must not be in the $J/\psi$ mass window ($|M_{\text{recoiling}}^{\gamma\gamma} - 3.097 \text{ GeV}/c^2| > 0.06 \text{ GeV}/c^2$). The invariant mass distribution of $\pi^0 \pi^+ \pi^- \pi^-$ of the selected events is shown in Fig. 3(a).

The $\pi^+ \pi^-$ invariant mass distribution in the $\chi_{c1}$ mass window (3.49 GeV/$c^2 < M_{\pi^+\pi^-} < 3.54 \text{ GeV}/c^2$) is shown in Fig. 3(b). A narrow structure around 980 MeV/$c^2$ is evident. The shaded histogram shows the $\pi^+ \pi^-$ invariant mass of events in the $\chi_{c1}$ sideband (3.39 GeV/$c^2 < M_{\pi^+\pi^-} < 3.45 \text{ GeV}/c^2$ and 3.54 GeV/$c^2 < M_{\pi^+\pi^-} < 3.59 \text{ GeV}/c^2$).

Exclusive MC samples of $\psi'$ decays which have similar final states are generated to check whether a peak near 980 MeV/$c^2$ can be produced in the $\pi^+ \pi^-$ mass spectrum.

The main possible backgrounds come from: $\psi' \rightarrow \gamma \chi_{c1} \rightarrow \gamma \gamma J/\psi \rightarrow \gamma \gamma \pi^+ \pi^- \pi^0  \pi^0 $; $\psi' \rightarrow \pi^+ \pi^- \pi^0  \pi^0 $; $\psi' \rightarrow \gamma \chi_{c1} \rightarrow \gamma a_0(980) \pi^+ \pi^- \pi^0  \pi^0 $; and $\psi' \rightarrow \eta \pi^+ \pi^- \pi^0  \pi^0 $. The $\pi^+ \pi^-$ invariant mass distributions from all these background channels is shown as the shaded histogram in Fig. 3(c), and there is no peak around 980 MeV/$c^2$.

A MC sample of $1.0 \times 10^6$ inclusive $\psi'$ decay events is used to investigate other possible backgrounds. The shaded area in Fig. 3(d) shows the $\pi^+ \pi^-$ invariant mass distribution of events selected from the inclusive MC sample. In the 980 MeV/$c^2$ region, there is no peaking background. The $f_0(980)$ from other $\psi' \rightarrow \gamma \chi_{c1} \rightarrow \gamma \pi^0 f_0(980)$ processes is much broader than the $a_0(980) \rightarrow f_0(980)$ mixing signal [14] and is estimated from the fit.

A simultaneous fit is performed to the $\pi^+ \pi^-$ invariant mass spectrum in the $\chi_{c1}$ mass window and the $\chi_{c1}$ sideband in a similar manner as in Sec. IV. The $f_0(980)$ contribution from other processes is represented by a Flatté formula.2 Figures 4(a) and 4(b) show the results of the simultaneous fit.

2The Flatté formula is quoted from Ref. [18]. The values of coupling constants and mass used here are quoted from BES II experiment results [14,20].
FIG. 4 (color online). Results of the simultaneous fit of the π⁺π⁻ mass spectra: (a) in the χ_{c1} mass window and (b) in the χ_{c3} sideband region. The solid curve is the result of fit described in the text. The dotted curve shows the mixing signal. The dash-dotted curve indicates f₀(980) from other processes. The dashed curves in (a) and (b) denote the background polynomial.

The fit yields \( N(α^0_0 \rightarrow f_0) = 6.4 ± 3.2 \) events for the mixing signal and \( N(f_0(980)) = 0.0 ± 8.6 \) events for the \( f_0(980) \) contribution from other processes. Comparing with the fit result without the \( f_0(980) \) contribution from other processes, the change in \( -lnL \) with \( Δ(d.o.f.) = 1 \) is 1.79, corresponding to a statistical significance of 1.9σ. Comparing with the fit result without the \( f_0(980) \) contribution from other processes, the change in \( -lnL \) with \( Δ(d.o.f.) = 1 \) is less than 0.01, corresponding to a statistical significance of less than 0.1σ. Using the Bayesian method, the upper limit for the number of the mixing events is 11.9, and the upper limit for the number of the \( f_0(980) \) events from other processes is 16.7 events at the 90% C.L. The results are listed in Table II.

The branching ratio of the mixing signal \( ψ' \rightarrow γχ_{c1} \rightarrow γπ^0α^0_0(980) \rightarrow γπ^0f_0(980) \rightarrow γπ^0π^+π^- \) is calculated as

\[
Br(ψ' \rightarrow γχ_{c1} \rightarrow γπ^0α^0_0(980) \rightarrow γπ^0f_0(980) \\
\rightarrow γπ^0π^+π^-) = \frac{N(α^0_0 \rightarrow f_0)}{e_{af} \cdot N_{ψ'} \cdot Br(π^0 \rightarrow γγ)},
\]

where \( N_{ψ'} \) is the total number of \( ψ' \) events and \( e_{af} = (22.3 ± 0.2)% \) is the efficiency for the mixing signal \( ψ' \rightarrow γχ_{c1} \rightarrow γπ^0α^0_0(980) \rightarrow γπ^0f_0(980) \rightarrow γπ^0π^+π^- \). The branching ratio is then determined to be \( (2.7 ± 1.4) \times 10^{-7} \), where the error is statistical only.

The total branching ratio of \( ψ' \rightarrow γχ_{c1} \rightarrow γπ^0π^+π^- \) is calculated as

\[
Br(ψ' \rightarrow γχ_{c1} \rightarrow γπ^0α^0_0(980) \rightarrow γπ^0f_0(980) \\
\rightarrow γπ^0π^+π^-) = \frac{N(α^0_0 \rightarrow f_0)/e_{af} + N(f_0)/e_{f}}{N_{ψ'} \cdot Br(π^0 \rightarrow γγ)},
\]

where \( e_{f} = (20.5 ± 0.2)% \) is the efficiency for the underlying process \( ψ' \rightarrow γπ^0f_0(980) \rightarrow γπ^0π^+π^- \). The branching ratio is then determined to be \( (2.7 ± 4.2) \times 10^{-7} \), where the error is statistical only.

If we fit the π⁺π⁻ invariant mass spectrum only with the mixing signal plus a 2nd order polynomial background, the fit yields \( 6.4 ± 3.2 \) events for the mixing signal. Comparing with the fit result with only the 2nd order polynomial, the change in \( -lnL \) with \( Δ(d.o.f.) = 1 \) is 4.41, corresponding to a statistical significance of 3.0σ. The upper limit at the 90% C.L. is 12.1 events.

If we assume there is no mixing and fit the π⁺π⁻ invariant mass spectrum only with the \( f_0(980) \) contribution from other processes plus a 2nd order polynomial, the fit yields \( 12.8 ± 6.7 \) events for the \( f_0(980) \) contribution from other processes. Comparing with the fit result with only the 2nd order polynomial, the change in \( -lnL \) with \( Δ(d.o.f.) = 1 \) is 2.62, corresponding to a statistical significance of 2.3σ. The upper limit at the 90% C.L. is 23.6 events. The fit results are listed in Table II. The total branching ratio of \( ψ' \rightarrow γχ_{c1} \rightarrow γπ^0f_0(980) \rightarrow γπ^0π^+π^- \) is calculated to be \( (6.0 ± 3.1) \times 10^{-7} \), where the error is statistical only.

VI. DISCUSSION

Various models for the a_0^0(980) and the f_0(980) [2–6] give different predictions for their coupling constants and masses; these have been measured by several experiments [19,21–25]. From these theoretical and experimental values of the resonance parameters, predictions for ξ_{a} and ξ_{\bar{a}} are calculated [13,14]. Using the parameter sets listed in Table III, the line shapes of the a_0^0(980) \rightarrow f_0(980) and f_0(980) \rightarrow a_0^0(980) mixing signals can be determined from MC simulation, and the underlying f_0(980) (a_0^0(980)) shapes can be parameterized accordingly. Table III shows the fitting results obtained using a similar fitting procedure as described in Secs. IV and V. The fitting results are consistent within the statistical error.

VII. SYSTEMATIC UNCERTAINTIES

The systematic uncertainties on the branching ratios are summarized in Table IV.

The systematic uncertainty associated with the tracking efficiency has been studied with control samples such as J/ψ \rightarrow ρπ, J/ψ \rightarrow p\bar{p}\pi^+\pi^−, and J/ψ \rightarrow K^+K^−K\bar{K}. The difference of the tracking efficiencies between data and MC simulation is 2% per charged track.

The uncertainties due to PID of π and K are determined from studies of control samples such as J/ψ \rightarrow ρπ, J/ψ \rightarrow p\bar{p}\pi^+\pi^−, and J/ψ \rightarrow K^+K^−K^+K^−\pi^0. The difference of the PID efficiency between data and MC is 2% per track.

</table>
The uncertainty due to photon detection and photon conversion is 1% per photon. This is determined from studies of the photon detection efficiency in control samples such as $J/\psi \rightarrow e^+ e^-$ and a study of photon conversion via $e^+ e^- \rightarrow \gamma \gamma$.

The uncertainty due to the $\pi^0$ selection is determined from a high purity control sample of $J/\psi \rightarrow \pi^+ \pi^- \pi^0$ decays. The $\pi^0$ selection efficiency is obtained from the change in the $\pi^0$ yield in the $\pi^0$ recoiling mass spectrum with or without the $\pi^0$ selection requirement. The difference of the $\pi^0$ reconstruction efficiency between data and MC simulation gives an uncertainty of 2.0% per $\pi^0$.

The uncertainty from the $\eta$ selection is 2.0% per $\eta$, which is determined in a similar way from a control sample of $J/\psi \rightarrow p\bar{p}\eta$.

The uncertainty of the kinematic fit for $J/\psi \rightarrow \phi f_0(980) \rightarrow \phi a_0^0(980) \rightarrow \phi \eta \pi^0$ is estimated from $J/\psi \rightarrow \omega \eta \rightarrow \pi^+ \pi^- \pi^0 \eta (\eta, \pi^0 \rightarrow \gamma \gamma)$. The efficiency is obtained from the change in the yield of $\omega$ signal by a fit to the $\pi^+ \pi^- \pi^0$ mass distribution with or without the requirement of the kinematic fit. The systematic uncertainty is determined to be 0.9%. The uncertainty of the kinematic fit for $\psi' \rightarrow \gamma X_{c1} \rightarrow \gamma \pi^0 a_0^0(980) \rightarrow \gamma \pi^0 f_0(980) \rightarrow \gamma \pi^0 \pi^+ \pi^-$ is estimated to be 1.7% from $\psi' \rightarrow \pi^+ \pi^- J/\psi, J/\psi \rightarrow \eta \gamma$.

The branching ratios for $\eta \rightarrow \gamma \gamma$, $\pi^0 \rightarrow \gamma \gamma$, and $\phi \rightarrow K^+ K^-$ decays are taken from the Particle Data Group [17]. The uncertainty on these branching ratios is taken as a systematic uncertainty in our measurements.

The total number of $J/\psi$ events is $(2.252 \pm 0.028) \times 10^8$, determined from inclusive $J/\psi$ hadronic decays [15], and the total number of $\psi'$ events is $(1.06 \pm 0.04) \times 10^8$, determined from inclusive $\psi'$ hadronic events [16]. The uncertainty on the number of $J/\psi$ events is 1.3%, and the uncertainty on the number of $\psi'$ events is 4%.

To estimate the systematic uncertainties due to the fit procedure, we repeat the fit with appropriate modifications to estimate the systematic uncertainties. The largest difference of the yield of each sources with respect to the values derived from the standard fit is considered as a systematic error. We change the sideband range and the order of the polynomial to estimate the uncertainty from the background shape. A series of fits using different fitting ranges is performed and the largest change of the branching ratios is assigned as a systematic uncertainty.

The total systematic uncertainties for the branching ratio measurements are obtained by adding up the contributions from all the systematic sources in quadrature.

The uncertainty due to the parameterization of the mixing signal line shape and the underlying $a_0^0(980)$ [$f_0(980)$] is kept separate and quoted as a second systematic uncertainty. The uncertainty is obtained by comparing the results with the parameter sets in Table III with the standard fit. We take this difference as a conservative estimate of the uncertainty and assign an uncertainty of 43.8% for the $a_0^0(980) \rightarrow f_0(980)$ mixing measurement and an uncertainty of 9.4% for the $f_0(980) \rightarrow a_0^0(980)$ mixing measurement. For the total branching ratio measurement of $J/\psi \rightarrow \phi a_0^0(980) \rightarrow \phi \eta \pi^0$, the uncertainty is estimated to be 38.3%, and for the total branching ratio measurement of $\psi' \rightarrow \gamma X_{c1} \rightarrow \gamma \pi^0 f_0(980) \rightarrow \gamma \pi^0 \pi^+ \pi^-$, the uncertainty is assigned to be 9.4%. If we assume there is no mixing, the uncertainties of the total branching ratio measurements are assigned to be 41.4% and 42.2%, respectively.

VIII. SUMMARY

Based on $(2.252 \pm 0.028) \times 10^8 J/\psi$ events and $(1.06 \pm 0.04) \times 10^8 \psi'$ events, the mixing branching ratios are measured to be $Br(J/\psi \rightarrow \phi f_0(980) \rightarrow \phi a_0^0(980) \rightarrow \phi \eta \pi^0) = (3.3 \pm 1.1(stat) \pm 0.4(sys) \pm 1.4(paras)) \times 10^{-6}$, $Br(\psi' \rightarrow \gamma X_{c1} \rightarrow \gamma \pi^0 a_0^0(980) \rightarrow \gamma \pi^0 f_0(980) \rightarrow \gamma \pi^0 \pi^+ \pi^-) = (2.7 \pm 1.4(stat) \pm 0.7(sys) \pm 0.3(paras)) \times 10^{-7}$, where the uncertainties are statistical, systematics due to this measurement, and systematics due to the parameterization, respectively.

The total branching ratio of $J/\psi \rightarrow \phi a_0^0(980) \rightarrow \phi \eta \pi^0$ is measured to be $(5.0 \pm 2.7(stat) \pm 1.7(sys) \pm 1.9(paras)) \times 10^{-6}$, and the total branching ratio of $\psi' \rightarrow \gamma X_{c1} \rightarrow \gamma \pi^0 f_0(980) \rightarrow \gamma \pi^0 \pi^+ \pi^-$ is measured to be $(2.7 \pm 4.2(stat) \pm 3.6(sys) \pm 0.3(paras)) \times 10^{-7}$. If we assume there is no mixing, the total branching ratios are measured to be $(9.7 \pm 2.2(stat) \pm 1.5(sys) \pm 4.0(paras)) \times 10^{-6}$ and $(6.0 \pm 3.1(stat) \pm 3.1(sys) \pm 2.5(paras)) \times 10^{-7}$, respectively.

When determining the upper limit of the number of $J/\psi \rightarrow \phi f_0(980) \rightarrow \phi a_0^0(980) \rightarrow \phi \eta \pi^0$ events, the uncertainties due to the fit range, background shape, the parameterization of mixing signal line shape, and the underlying $a_0^0(980)$ are considered. Using the Bayesian method, different upper limits at the 90% C.L. are determined by varying the fit range, the background shape and the parameterization of the mixing signal line shape, and the underlying $a_0^0(980)$ in Table III. The upper limit for the mixing signal is taken to be the largest of them: $N_{f_0}^{UL} = 39.7$ events. A conservative estimate of the upper limit of the branching ratio is determined by lowering the efficiency by 1 standard deviation.

The upper limit on the branching ratio at the 90% C.L. is calculated as

$$Br(J/\psi \rightarrow \phi f_0(980) \rightarrow \phi a_0^0(980) \rightarrow \phi \eta \pi^0) < \left(\frac{\sigma_{f_0}^{UL}}{\sigma_{f_0}^{UL}}\right) \cdot N_{f_0/\psi} \cdot Br(\phi \rightarrow K^+ K^-) \cdot Br(\eta \rightarrow \gamma \gamma) \cdot Br(\pi^0 \rightarrow \gamma \gamma)$$
Similarly, considering the uncertainties due to fit range, background shape, the parameterization of mixing signal line shape, and the underlying $f_0(980)$, the upper limit number of the mixing signal $\psi' \rightarrow \gamma \chi_{c1} \rightarrow \gamma \pi^0 a_0^0(980) \rightarrow \gamma \pi^0 f_0(980) \rightarrow \gamma \pi^0 \pi^+ \pi^-$ is determined to be $N_{a_{f_0}}^{UL} = 13.0$ events.

The uncertainty from where the uncertainties are statistical, systematics due to this measurement and the parameterization, respectively. The uncertainty from $\text{Br}(\psi' \rightarrow \gamma \chi_{c1} \rightarrow \gamma \pi^0 a_0^0(980) \rightarrow \gamma \pi^0 f_0(980))$ is

$$\xi_{a_{f_0}} = \frac{\text{Br}(J/\psi \rightarrow \phi f_0(980) \rightarrow \phi a_0^0(980) \rightarrow \phi \eta \pi^0)}{\text{Br}(J/\psi \rightarrow \phi f_0(980) \rightarrow \phi \pi^+ \pi^-)} = (0.60 \pm 0.20(\text{stat})) \pm 0.12(\text{sys}) \pm 0.26(\text{para})\%,$$

where the uncertainties are statistical, systematics due to this measurement, and the parameterization, respectively. The uncertainty from $\text{Br}(\psi' \rightarrow \gamma \chi_{c1} \rightarrow \gamma \pi^0 a_0^0(980) \rightarrow \gamma \pi^0 \pi^+ \pi^-)$ is included as a part of the systematic error. The upper limit of the mixing intensity $\xi_{a_{f_0}}$ at the 90% C.L. is 1.1%.

The mixing intensity $\xi_{af}$ for the $a_0^0(980) \rightarrow f_0(980)$ transition is calculated to be

$$\xi_{af} = \frac{\text{Br}(\psi' \rightarrow \gamma \chi_{c1} \rightarrow \gamma \pi^0 a_0^0(980) \rightarrow \gamma \pi^0 f_0(980) \rightarrow \gamma \pi^0 \pi^+ \pi^-)}{\text{Br}(\psi' \rightarrow \gamma \chi_{c1} \rightarrow \gamma \pi^0 a_0^0(980) \rightarrow \gamma \pi^0 \pi^+ \pi^-)} = (0.31 \pm 0.16(\text{stat}) \pm 0.14(\text{sys}) \pm 0.03(\text{para})\%.$$

The uncertainty from $\text{Br}(\psi' \rightarrow \gamma \chi_{c1} \rightarrow \gamma \pi^0 a_0^0(980) \rightarrow \gamma \pi^0 \pi^+ \pi^-)$ is included as a part of the systematic error. The upper limit of the mixing intensity $\xi_{af}$ at the 90% C.L. is 1.1%.

The calculated mixing intensities [14] with the resonance parameters from various models [2–6] and experimental measurements [19,21–25] are compared with our results in Fig. 5. This result will be very useful in pinning down the resonance parameters of $a_0^0(980)$ and $f_0(980)$.
