Authors’ contributions

This work was carried out in collaboration between all authors. All authors read and approved the final manuscript.

ABSTRACT

Background: Esophageal cancer is one of the most deadly malignancies worldwide and esophageal squamous cell carcinoma (ESCC) is the most frequent type. Methods: We identified up-regulated genes from gene expression profiles of HKESC-4 cell line, its parental tumor tissues, non-tumoral esophageal epithelia and lymph nodes with metastatic carcinoma using Human Genome U133 Plus 2.0 microarray. Results: Four genes [High-mobility group AT-hook 2 (HMGA2), paternally expressed 10 (PEG10), SH3 and multiple ankyrin repeat domains 2 (SHANK2) and WNT1 inducible signaling pathway protein 3 (WISP3)] were selected for further validation with real-time quantitative polymerase chain reaction (qPCR) in a panel of ESCC cell lines and clinical specimens. HMGA2 was found to be overexpressed in the panel of ESCC cell lines tested. By using immunohistochemistry, HMGA2 was found to be up-regulated in 70% of ESCC tissues (21 out of 30 cases).

*Corresponding author: Email: slaw@hkucc.hku.hk
Conclusion: This study demonstrates successful use of gene microarray to identify and reveal HMGA2 as a novel and consistently overexpressed gene in ESCC cell lines and clinical samples.

Keywords: Esophageal cancer; microarray; HMGA2; PEG10; SHANK2; WISP3.

1. INTRODUCTION

Esophageal cancer ranks fifth as the most common cause of cancer-related deaths in men worldwide, causing about 400,000 deaths annually [1]. The incident rate is higher in Southern and Eastern Africa and Eastern Asia when compared to Western and Middle Africa and Central America [1]. This cancer comprises two major types, namely esophageal squamous cell carcinoma (ESCC) and adenocarcinoma, the former is more common and contributes to about 90% of cases in high-risk regions [1]. Patients with ESCC usually have poor prognosis largely because of late diagnosis of the disease [2]. Despite advances in surgical techniques combined with various treatment modalities, such as radiotherapy and chemotherapy, the overall 5-year survival rate remains at 20-30% [3]. To alleviate this clinical situation, the development of new treatment modalities, diagnostic technologies and preventative measures is required, which cannot be accomplished without understanding the underlying mechanisms of esophageal carcinogenesis. The development of gene microarray technology allows comprehensive comparison of gene expression profiles in various pathophysiological processes, such as enabling the comparison of gene profiles between cancer and normal conditions. In the present study, we took advantage of this technology to identify differentially expressed genes in cancerous and non-cancerous conditions in esophagus, followed by further validation for the involvement of these genes in ESCC.

2. MATERIALS AND METHODS

2.1 HKESC-4 Cell Line and Clinical Specimens for Microarray

HKESC-4, a human ESCC cell line of Chinese origin, was established previously in our laboratory and the culture conditions for this cell line were as described elsewhere [4]. Cultured HKESC-4 cells were harvested at 80% confluency at passage 30 for extracting RNA. Parental tumoral tissue (T), from which HKESC-4 cell line was derived, and its corresponding non-tumoral epithelium (N) and lymph node containing metastatic carcinoma (LN) were isolated during esophagectomy and snap-frozen until their use for RNA extraction. The extracted RNA of the cell line (HKESC-4) and clinical specimens (T, N and LN) was subjected to gene microarray. Consent regarding the use of clinical specimens for this study was obtained from Institutional Review Board of The University of Hong Kong/Hospital Authority Hong Kong West Cluster (HKU/HA HKW IRB).

2.2 Clinical Tissues and ESCC Cell Lines for Quantitative Real-Time Polymerase Chain Reaction (qPCR)

In addition to the clinical specimens for gene microarray as mentioned above, three non-tumoral tissues were obtained from esophageal epithelium at least 5 cm away from the tumor of other patients during surgical resection (Non-T). Apart from HKESC-4 cell line, HKESC-1, HKESC-2, HKESC-3 and SLMT-1 cell lines were included and used as described elsewhere [4-6]. These cells were cultured in minimal essential medium (Invitrogen,
Carlsbad, CA, USA) supplemented with 10% fetal bovine serum (Invitrogen) and 1% penicillin-streptomycin. Cell cultures were maintained in a humidified incubator at 37°C containing 5% carbon dioxide (CO$_2$). Monolayer cells at 80% confluency were harvested and used for RNA extraction.

2.3 RNA Extraction for qPCR

RNA extraction was performed as described [7]. In brief, 1 ml TRIzol reagent (Invitrogen) was used to lyse tissues or cells for RNA extraction. Chloroform was used for phase separation. After centrifugation, the upper aqueous phase with RNA was collected and transferred to RNase-free tubes containing 0.5 ml isopropyl alcohol for RNA precipitation. RNA pellets were then washed with 75% RNase-free ethanol. Finally, RNA pellets were dissolved in RNase-free water. DNase I digestion was performed before the concentration of RNA was determined by measuring its absorbance at 260 nm and A$_{260}$/A$_{280}$ ratio.

2.4 Gene Microarray

RNA of HKESC-4 cells and clinical specimens were subjected to gene expression profiling using GeneChip Human Genome U133 Plus 2.0 Array (Affymetrix, Santa Clara, CA, USA). This GeneChip enables the analysis of over 47,000 human transcripts and variants. The whole procedure of RNA quality control, microarray labeling, GeneChip hybridization and data acquisition was performed at the Genome Research Centre, The University of Hong Kong, Hong Kong, PRC under standardized condition. The statistical analysis to identify differentially expressed genes was performed using MicroArray Suite software (Affymetrix).

2.5 Synthesis of Complementary DNA (cDNA)

RNA was reverse-transcribed into cDNA using High Capacity cDNA Reverse Transcription Kit (Applied Biosystems, Invitrogen), according to the manufacturer’s protocol. Briefly, DNase-treated RNA was diluted with RNase-free water to reach a final concentration of 250 ng in 10 μl. Diluted RNA was then mixed with 2 μl 10X RT buffer, 0.8 μl 25X dNTP Mix (100 mM), 2 μl 10X RT Random Primers, 1 μl MultiScribe Reverse Transcriptase (50 U/μl), 1 μl RNase Inhibitor and 3.2 μl nuclease-free water. The reaction was then incubated at 25°C for 10 minutes, followed by 37°C for 2 hours and 85°C for 5 seconds to inactivate the activities of the reverse transcriptase and to completely denature the template.

2.6 qPCR

The procedure for qPCR was followed as described elsewhere [8, 9]. In brief, qPCR was performed using cDNA of each sample, gene-specific primers (Table 1) and Platinum SYBR Green qPCR SuperMix-UDG (Invitrogen), according to the protocol from the manufacturer. The reactions were run for 50 cycles at 94°C for 10 minutes, 95°C for 90 seconds and 72°C for 90 seconds in an ABI PRISM 7700 Sequence Detector (Applied Biosystems). Cycle threshold (C$_T$) values of each reaction were obtained using Sequence Detection System (SDS) Software Version 1.9.1. For each reaction, the expression of each gene was normalized against the expression of the housekeeping gene β-actin. The relative expression of each gene was calculated based on a comparative C$_T$ equation and is presented as the value of relative intensity.

2.7 Statistical Analysis for qPCR Data

Statistical analysis was performed as described elsewhere [10]. One-way ANOVA followed by Duncan's multiple range test was used to determine statistical significance. Each sample was run in triplicates. The relative value is presented as the mean ± standard error of the mean (S.E.M.). p-Values less than 0.05 were considered statistically significant. Statistical analysis was performed with Statistical Package for the Social Sciences version 17 (IBM, New York, USA).

2.8 Immunohistochemistry

Immunohistochemistry was performed using the avidin-biotin method [11, 12]. Five-micrometer paraffin sections were prepared on gelatin-coated glass slides. Sections were preheated at 60°C for 20 minutes, deparaffinized in xylene and rehydrated through graded alcohol. Antigen retrieval was carried out by heating the sections in 0.2 M citrate buffer (pH 6) in a microwave oven at 95°C for 5 minutes. After cooling for 30 minutes, the sections were treated with 0.3% hydrogen peroxide at room temperature for 30 minutes to block endogenous peroxidase activity. Non-specific binding sites on sections were blocked with 1X TBS with 2% bovine serum albumin (BSA; Sigma-Aldrich, St Louis, MO, USA) and 2% normal goat serum (Invitrogen) at room temperature for 30 minutes. HMGA2-specific rabbit polyclonal antibody (1:100) (Santa Cruz Biotechnology, Santa Cruz, CA, USA) was applied to the sections and the reaction was incubated at room temperature for 30 minutes. After washing three times with 1X TBS for 5 minutes each, the sections were incubated with biotinylated anti-rabbit secondary antibody (EnVision Systems; Dako, Glostrup, Denmark) at room temperature for 30 minutes. To visualize the signals, the sections were washed and stained with avidin-biotin complex and 3, 3'-diaminobenzene (DAB) at room temperature. Lastly, the sections were counterstained with hematoxylin. The expressions of HMGA2 were evaluated by Dr. AK Lam, a qualified pathologist, under light microscope.

3. RESULTS

3.1 Identification of Differentially Expressed Genes Using Gene Microarray

Gene microarray analysis revealed 3,081 genes, 4,027 genes and 3,590 genes having more than 2-fold induction in T, LN and HKESC-4 cells when compared to N. For down-regulated genes with more than 2-fold difference, 4,808 genes, 6,052 genes and 5,846 genes were
found in T, LN and HKESC-4 cells in comparison with N. For those up-regulated genes in T, LN and HKESC-4, 43 of them had more than 10-fold induction (Table 2). Among them, 34 genes (CAMK2A, CART1, CCNA1, COCH, FLJ33516, FMN2, FOXD1, FOXG1B, GPR, HMGA2, HOXC10, HOXC11, HTR2C, IMP-3, LOC163782, MAGEB2, MFAP2, MGC17986, MGC27005, NBEA, NKG2-2, PCDHB5, PEG10, PPN2, POPDC3, PPFIA1, PRAME, SAGE1, SHANK2, SIX1, SLCO1B3, SYT1, TP53TG3 and WISP3) were first identified to be overexpressed in ESCC, while 13 of them (DKK1, EGFR, EMS1, GAL, HCG4, LAMC2, MAGEA1, MAGEA4, MAGEA11, MMP13, PTHLH, ZIC and ZNF595) have previously been reported to be overexpressed in ESCC (Table 3). Among the 34 newly identified genes, HMGA2, PEG10, SHANK2 and WISP3 were further selected for validation due to their potential involvement in tumorigenesis based on literature search.

3.2 Gene Expression of HMGA2

High expression of HMGA2 in N, T, LN and HKESC-4 observed in gene microarray was confirmed using qPCR, such that the relative intensities of HMGA2 expression in N, T, LN and HKESC-4 obtained using these two methods were comparable (fold change by gene microarray: 1, 31, 63 and 18 versus 1, 26, 49 and 33 by qPCR). Moreover, increased gene expression of HMGA2 was also detected in four ESCC cell lines (HKESC-1, HKESC-2, HKESC-3 and SLMT-1). Significantly higher gene expression on average of 20-fold of HMGA2 was noted in ESCC cell lines when compared to N and Non-T (Fig. 1A).

3.3 Gene Expression of PEG10

An over-expression of PEG10 in ESCC observed in gene microarray was confirmed using qPCR. The relative intensities of PEG10 in N, T, LN and HKESC-4 cells were 1, 20, 28 and 28 by gene microarray, while their relative intensities were 1, 45, 148 and 269 by qPCR, respectively. However, no significant difference in the average gene expression of PEG10 was detected in tested ESCC cell lines when compared to N and Non-T, despite their having an average of 100-fold induction in gene expression of PEG10 (Fig. 1B).

3.4 Gene Expression of SHANK2

High gene expression of SHANK2 in ESCC observed in gene microarray was confirmed using qPCR. The relative intensities of SHANK2 in N, T, LN and HKESC-4 cells were 1, 30, 20 and 20 by gene microarray and 1, 21, 11 and 19 by qPCR, respectively. No significant difference in the gene expression of SHANK2 was detected in ESCC cells when compared to N (Fig. 1C).

3.5 Gene Expression of WISP3

High gene expression of WISP3 in ESCC detected using gene microarray was confirmed using qPCR. The relative intensities of gene expression of WISP3 in N, T, LN and HKESC-4 cells were 1, 37, 53 and 26 by gene microarray and 1, 152, 117 and 117 by qPCR, respectively. A significant increase in the gene expression of WISP3 was detected in HKESC-2 cells (Fig. 1D).
3.6 Protein Expression of HMGA2 in ESCC Tissues

Immunohistochemical data show the localization of HMGA2 in the nuclei of the ESCC tissues (Fig. 2). Overexpression of HMGA2 was found in 70% ESCC tissues (21 out of 30 cases) when the expression of HMGA2 was examined in 30 pairs of tumoral tissues and adjacent non-tumoral tissues. No detectable level of HMGA2 expression was observed in the non-tumoral tissues (data not shown).

Fig. 1. Gene expressions of HMGA2 (A), PEG10 (B), SHANK2 (C) and WISP3 (D) relative to β-actin have been shown in clinical tissues and ESCC cell lines. The value of N is arbitrarily set to 1 for comparison.
Fig. 2. Immunohistochemical staining of HMGA2 in ESCC tissues. Original magnification, 200X (A, C and E); 400X (B, D and F)
4. DISCUSSION

In the present study, to our knowledge, the gene microarray and real-time qPCR analysis showed the presence of HMGA2 mRNA expression in human esophageal tissues for the first time. HMGA2 mRNA overexpression was detected in ESCC cell lines compared with the corresponding morphologically non-tumoral esophageal epithelial tissues. The current findings showed that overexpression of HMGA2 gene appears to be a consistent feature in ESCC. The protein expression of HMGA2 was further validated in ESCC specimens by immunohistochemistry. Liu et al. have shown an elevated level of HMGA2 protein in ESCC tissues by comparing 150 pairs of tumor and adjacent non-tumor tissues in patients [21], for which this data are in line with our findings reported here. The immunostaining analysis showed that HMGA2 protein expression was localized in the nuclei of the ESCC cells. The majority of ESCC cases (21/30, 70%) were found to have significantly enhanced expression of HMGA2 compared with morphologically normal esophageal epithelium.

HMGA2 belongs to the HMGA family, which also contains two other members HMGA1A and HMGA1B. HMGA protein family members are small nuclear proteins. A prominent feature of the HMGA family is the three DNA-binding domains termed AT-hooks at the N-terminal region that bind the minor groove of AT-rich DNA sequences. These proteins play key roles in chromatin architecture and gene control by serving as generalized chromatin effectors, either enhancing or suppressing the ability of transcriptional factors in the process of transcriptional regulation. HMGA2 expression was found to be restricted during embryogenesis, whereas it is absent or has low expression in normal adult tissues [22]. However, overexpression of HMGA2 has been reported in various types of human cancer including of the pituitary [23], oral cavity [24], lung [25], breast [26], pancreas [27], and nerves [28]. In addition, HMGA2 protein was reported to be ectopically expressed at the invasive front of oral carcinomas and had a significant impact on tumor progression and patient survival [24]. Similarly, HMGA proteins were found to be expressed in lung carcinomas and their expressions were inversely associated with survival, providing a potentially useful marker for diagnosis and prognosis of lung cancer [29].

Overexpression of HMGA2 gene leads to pituitary adenomas in mice. The mechanism has been described by Fedele et al. [30]. HMGA2 binds to the pRB A/B pocket domain, while it does not compete with the E2F1 protein. Conversely, E2F1 activation by HMGA2 occurs by displacing HDAC1 from the pRB/E2F1 complex, resulting in enhanced acetylation of both E2F1 and DNA-associating histones, thereby promoting E2F1 activation [30]. It is well-known that pRB controls cell cycle progression through its interaction with the E2F family of transcription factors, whose activity is crucial for the expression of several genes required for cells to enter the S phase of the cell cycle [31]. By repressing E2F1 activity, pRB protein prevents cell from progressing beyond the G1 phase of the cell cycle. If the repression of E2F1 is relieved by phosphorylation or viral transformation of pRB [32, 33], resulting in the release of E2F1, the transcription of its target genes is activated [34]. This allows cells to progress toward S phase. The overexpressions of pRB [35] and E2F1 [36] were also found in ESCC specimens. These findings are consistent with the mechanism in pituitary cancer described by Fedele et al. [22]. This suggests that the pRB/E2F1 pathway involving HMGA2 may also play a critical role in the pathogenesis of ESCC.
5. CONCLUSION

In summary, the gene microarray results show a comprehensive picture of the differential gene expression in ESCC. Thirty-four novel overexpressed genes were revealed in this study. The real-time qPCR results confirmed that HMGA2 was up-regulated in all the ESCC cell lines examined. In addition, the protein expression of HMGA2 demonstrated a significantly higher incidence of overexpression in primary ESCCs than morphologically non-tumoral esophageal epithelium tissue. For the first time, the present findings showed that HMGA2 was overexpressed in ESCC, and suggest that the activation of HMGA2 might be important in the pathogenesis of ESCC.

CONSENT

All authors declare that written informed consent was obtained from the patient for publication of this case report and accompanying images.

ETHICAL APPROVAL

All authors hereby declare that all experiments have been examined and approved by the appropriate ethics committee and have therefore been performed in accordance with the ethical standards laid down in the 1964 Declaration of Helsinki.

COMPETING INTERESTS

Authors have declared that no competing interests exist.
