Abstract

In this paper, we consider the optimal proportional reinsurance strategy in a risk model with two dependent classes of insurance business, where the two claim number processes are correlated through a common shock component. Under the criterion of maximizing the expected exponential utility with the variance premium principle, we adopt a nonstandard approach to examining the existence and uniqueness of the optimal reinsurance strategy. Using the technique of stochastic control theory, closed-form expressions for the optimal strategy and the value function are derived for the compound Poisson risk model as well as for the Brownian motion risk model. From the numerical examples, we see that the optimal results for the compound Poisson risk model are very different from those for the diffusion model. The former depends not only on the safety loading, time, and the interest rate, but also on the claim size distributions and the claim number processes, while the latter only depends on the safety loading, time, and the interest rate.

Keywords: Brownian motion; Common shock; Compound Poisson process; Diffusion process; Exponential utility; Hamilton-Jacobi-Bellman equation; Proportional reinsurance
1 Introduction

With reinsurance, insurers are able to transfer some of their risks to another party at the expense of making less potential profit, and hence finding optimal reinsurance strategy to balance their risk and profit is of great interest to them. In fact, optimal reinsurance problems have gained much interest in the actuarial literature in the past few years, and the technique of stochastic control theory and the Hamilton-Jacobi-Bellman equation are frequently used to cope with these problems. See, for example, Schmidli (2001), Irgens and Paulsen (2004), Promislow and Young (2005), Liang et al. (2011), and Liang and Young (2012).

In the study of optimal reinsurance contracts, a few objective functions are commonly seen in the literature. Browne (1995), Schmidli (2002), Liang (2007), and Luo et al. (2008) consider the objective function that minimizes ruin probability. Kaluszka (2001, 2004) study the optimal reinsurance problem under various mean-variance premium principles of the reinsurer. Since explicit expression for the ruin probability is difficult to derive when the underlying risk follows a compound Poisson process, some papers including Centeno (1986, 2002), Hald and Schmidli (2004), and Liang and Guo (2007, 2008) focus on constructing optimal contracts that maximize the adjustment coefficient by the martingale approach. Moreover, Cai and Tan (2007), Cai et al. (2008), and Bernard and Tian (2009) adopt the criteria of minimizing tail risk measures such as value at risk and conditional tail expectation. In this paper, our objective is to maximize the expected utility of terminal wealth which is another popular criterion for various optimization problems in finance and modern risk theory. For example, see Liang et al. (2012) and references therein.

Although research on optimal reinsurance is increasing rapidly, only a few papers deal with the problem in relation to dependent risks. Under the criteria of maximizing the expected utility of terminal wealth and maximizing the adjustment coefficient, Centeno (2005) studies the optimal excess of loss retention limits for two dependent classes of insurance risks. Bai et al. (2012) also seek the optimal excess of loss reinsurance to minimize the ruin probability for the diffusion risk model. Under the variance premium principle, the optimal reinsurance contract is not necessarily an excess of loss reinsurance but a proportional reinsurance (see Proposition 7 in Hipp and Taksar (2010)). These papers motivate us to consider the optimal proportional reinsurance with dependent risks under the variance premium principle. By a nonstandard approach, we investigate the conditions of existence and uniqueness of the optimal reinsurance strategies. Using the technique of stochastic control theory, closed-form expressions for the optimal reinsurance strategy and the value function
are derived for the compound Poisson risk model as well as for the diffusion risk model. From
the numerical examples, we find that the optimal results in the compound Poisson case are very
different from those in the diffusion case. The former depends not only on the safety loading, time,
and interest rate, but also on the claim size distributions and the counting processes, while the
latter only depends on the safety loading, time, and interest rate.

The rest of the paper is organized as follows. In Section 2, the models and assumptions are
presented. In Sections 3 and 4, we discuss the optimal strategies in both the compound Poisson and
diffusion cases, and derive closed form expressions for the optimal results. In Section 5, numerical
examples are carried out to assess the impact of some model parameters on the optimal strategies.
Finally, we conclude the paper in Section 6.

2 Model formulation

Suppose that an insurance company has two dependent classes of insurance business such as motor,
health, and life insurance. Let \( X_i \) be the claim size random variables for the first class with common
distribution \( F_X(x) \) and \( Y_i \) be the claim size random variables for the second class with common
distribution \( F_Y(y) \). Their means are denoted by \( \mu_1 = E(X_i) \) and \( \mu_2 = E(Y_i) \). Assume that
\( F_X(x) = 0 \) for \( x \leq 0 \), \( F_Y(y) = 0 \) for \( y \leq 0 \), \( 0 < F_X(x) < 1 \) for \( x > 0 \), \( 0 < F_Y(y) < 1 \) for \( y > 0 \),
and that their moment generating functions, \( M_X(r) \) and \( M_Y(r) \), exist. Then, the aggregate claims
processes for the two classes are given by

\[
S_1(t) = \sum_{i=1}^{M_1(t)} X_i \quad \text{and} \quad S_2(t) = \sum_{i=1}^{M_2(t)} Y_i,
\]

where \( M_i(t) \) is the claim number process for class \( i \) (\( i = 1, 2 \)). It is assumed that \( X_i \) and \( Y_i \) are
independent claim size random variables, and that they are independent of \( M_1(t) \) and \( M_2(t) \).

The two claim number processes are correlated in the way that

\[
M_1(t) = N_1(t) + N(t) \quad \text{and} \quad M_2(t) = N_2(t) + N(t),
\]

with \( N_1(t), N_2(t), \) and \( N(t) \) being three independent Poisson processes with parameters \( \lambda_1, \lambda_2, \) and
\( \lambda \), respectively. Therefore, the aggregate claims process generated from the two classes of business
has the form

\[
S_t = \sum_{i=1}^{N_1(t)+N(t)} X_i + \sum_{i=1}^{N_2(t)+N(t)} Y_i.
\]
We assume that both $E(X e^{rX}) = M'_X(r)$ and $E(Y e^{rY}) = M'_Y(r)$ exist for $0 < r < \zeta$, and that both $\lim_{r\to\zeta} E(X e^{rX})$ and $\lim_{r\to\zeta} E(Y e^{rY})$ tend to $\infty$ for some $0 < \zeta \leq +\infty$. It is obvious that the dependence of the two classes of business is due to a common shock governed by the counting process $N(t)$. This model has been studied extensively in the literature; see for example, Yuen et al. (2002, 2006).

As usual, we define the surplus process

$$R_t = u + ct - S_t,$$

where $u$ is the amount of initial surplus, and $c$ is the rate of premium. Moreover, we allow the insurance company to continuously reinsure a fraction of its claim with the retention levels $q_{1t} \in [0, 1]$ and $q_{2t} \in [0, 1]$ for $X_i$ and $Y_i$, respectively. Let the reinsurance premium rate at time $t$ be $\delta(q_{1t}, q_{2t})$. Furthermore, the company is allowed to invest all its surplus in a risk free asset with interest rate $r$. Let $\{R^{q_1,q_2}_t, t \geq 0\}$ denote the associated surplus process, i.e., $R^{q_1,q_2}_t$ is the wealth of the insurer at time $t$ under the strategy $(q_{1t}, q_{2t})$. This process then evolves as

$$dR^{q_1,q_2}_t = [rR^{q_1,q_2}_t + (c - \delta(q_{1t}, q_{2t}))]dt - q_{1t}a_1dt - q_{2t}a_2dt.$$ (2.1)

From Grandell (1991), we know that the Brownian motion risk model given by

$$\hat{S}_1(t) = a_1t - \sigma_1B_{1t},$$

with $a_1 = (\lambda_1 + \lambda)E(X)$ and $\sigma^2_1 = (\lambda_1 + \lambda)E(X^2)$ can be seen as a diffusion approximation to the compound Poisson process $S_1(t)$. Similarly,

$$\hat{S}_2(t) = a_2t - \sigma_2B_{2t},$$

with $a_2 = (\lambda_2 + \lambda)E(Y)$ and $\sigma^2_2 = (\lambda_2 + \lambda)E(Y^2)$ can be treated as a diffusion approximation to the compound Poisson process $S_2(t)$. Here, $B_{1t}$ and $B_{2t}$ are standard Brownian motions with the correlation coefficient

$$\rho = \frac{\lambda E(X)E(Y)}{\sqrt{(\lambda_1 + \lambda)E(X^2)(\lambda_2 + \lambda)E(Y^2)}}.$$ 

So, $E[B_{1t}B_{2t}] = \rho t$. Replacing $S_i(t)$ ($i = 1, 2$) of (2.1) by $\hat{S}_i(t)$ ($i = 1, 2$), one can obtain the following surplus process

$$d\hat{R}^{q_1,q_2}_t = [r\hat{R}^{q_1,q_2}_t + (c - \delta(q_{1t}, q_{2t})) - q_{1t}a_1 - q_{2t}a_2]dt + q_{1t}\sigma_1dB_{1t} + q_{2t}\sigma_2dB_{2t},$$
or equivalently,
\[
d\hat{R}_{t}^{q_1,q_2} = [r\hat{R}_{t}^{q_1,q_2} + (c - \delta(q_{1t}, q_{2t})) - q_{1t}a_1 - q_{2t}a_2]dt \\
+ \sqrt{\sigma_1^2 q_{1t}^2 + \sigma_2^2 q_{2t}^2 + 2\sigma_1 \sigma_2 q_{1t} q_{2t} \rho} dB_t,
\]
(2.2)

where \( B_t \) is a standard Brownian motion.

**Remark 2.1.** It follows from Yuen et al. (2002) or Wang and Yuen (2005) that \( S_t \) is also a compound Poisson process with parameter \( \tilde{\lambda} = \lambda_1 + \lambda_2 + \lambda \), and that the distribution of the transformed claim size random variable \( X' \) is given by

\[
F_{X'}(x) = \lambda_1 \tilde{\lambda} F_X(x) + \lambda_2 \tilde{\lambda} F_Y(x) + \frac{\lambda}{\tilde{\lambda}} F_{X+Y}(x).
\]

Therefore, the Brownian motion risk model given by

\[
\hat{S}_t = (a_1 + a_2)t - \sqrt{\sigma_1^2 + \sigma_2^2 + 2\lambda \mu_1 \mu_2} B_t
\]
can be seen as a diffusion approximation to the compound Poisson process \( S_t \). On the other hand,

\[
\hat{S}_1(t) + \hat{S}_2(t) = (a_1 + a_2)t - (\sigma_1 B_{1t} + \sigma_2 B_{2t}),
\]

which can be replaced by

\[
\hat{S}_1(t) + \hat{S}_2(t) = (a_1 + a_2)t - \sqrt{\sigma_1^2 + \sigma_2^2 + 2\sigma_1 \sigma_2 \rho} B_t,
\]
as the two forms have the same distributional properties. Hence, the sum \( \hat{S}_1(t) + \hat{S}_2(t) \) can also be regarded as a diffusion approximation to the compound Poisson process \( S_t \) when

\[
\rho = \frac{\lambda E(X)E(Y)}{\sqrt{(\lambda_1 + \lambda)E(X^2)(\lambda_2 + \lambda)E(Y^2)}} = \frac{\lambda \mu_1 \mu_2}{\sigma_1 \sigma_2}.
\]

Assume now that the insurer is interested in maximizing the expected utility of terminal wealth, say at time \( T \). The utility function is \( u(x) \), which satisfies \( u' > 0 \) and \( u'' < 0 \). Then, the objective functions are

\[
J^{q_1,q_2}(t, x) = E[u(R_{T_t}^{q_1,q_2}) | R_{t}^{q_1,q_2} = x],
\]
(2.3)

and

\[
J^{\hat{q}_1,q_2}(t, x) = E[u(\hat{R}_{T_t}^{q_1,q_2}) | \hat{R}_{t}^{q_1,q_2} = x].
\]
(2.4)
Since (2.3) and (2.4) will be discussed separately, the use of the same notation \( J^{q_1,q_2}(t,x) \) will not cause any confusion. The corresponding value function is then given by

\[
V(t,x) = \sup_{q_1,q_2} J^{q_1,q_2}(t,x).
\]  

(2.5)

We assume that the insurer has an exponential utility function

\[
u(x) = -\frac{m}{\nu} e^{-\nu x},\]

for \( m > 0 \) and \( \nu > 0 \). This utility has constant absolute risk aversion (CARA) parameter \( \nu \). Such a utility function plays an important role in insurance mathematics and actuarial practice as this is the only function under which the principle of “zero utility” gives a fair premium that is independent of the level of reserve of an insurance company (see Gerber (1979)).

Let \( C^{1,2} \) denote the space of \( \phi(t,x) \) such that \( \phi \) and its partial derivatives \( \phi_t, \phi_x, \phi_{xx} \) are continuous on \([0,T] \times R\). To solve the above problem, we use the dynamic programming approach described in Fleming and Soner (2006). From the standard arguments, we see that if the value function \( V \in C^{1,2} \), then \( V \) satisfies the following Hamilton-Jacobi-Bellman (HJB) equation

\[
\sup_{q_1,q_2} A^{q_1,q_2} V(t,x) = 0,
\]

(2.6)

for \( t < T \) with the boundary condition

\[
V(T,x) = \nu(x),
\]

(2.7)

where

\[
A^{q_1,q_2} V(t,x) = V_t + [r x + c - \delta(q_1,q_2)] V_x + \lambda_1 E[V(t,x - q_1 X) - V(t,x)] + \lambda_2 E[V(t,x - q_2 Y) - V(t,x)] + \lambda E[V(t,x - q_1 X - q_2 Y) - V(t,x)],
\]

for the risk process (2.1), and

\[
A^{q_1,q_2} V(t,x) = V_t + [r x + c - \delta(q_1,q_2) - q_1 a_1 - q_2 a_2] V_x + \frac{1}{2} (\sigma_1^2 q_1^2 + \sigma_2^2 q_2^2 + 2 q_1 q_2 \lambda \mu_1 \mu_2) V_{xx},
\]

for the risk process (2.2).

Using the standard methods of Fleming and Soner (2006) and Yang and Zhang (2005), we have the following verification theorem:
Theorem 2.1. Let $W \in C^{1,2}$ be a classical solution to (2.6) that satisfies (2.7). Then, the value function $V$ given by (2.5) coincides with $W$. That is,

$$W(t, x) = V(t, x).$$

Furthermore, set $(q_1^*, q_2^*)$ such that

$$\mathcal{A}q_1^* q_2^* V(t, x) = 0$$

holds for all $(t, x) \in [0, T) \times R$. Then, $(q_1^*(t, R_t^1), q_2^*(t, R_t^2))$ is the optimal strategy. Here, $R_t^*$ is the surplus process under the optimal strategy.

Remark 2.2. In this paper, we assume that continuous trading is allowed and that all assets are infinitely divisible. We work on a complete probability space $(\Omega, \mathcal{F}, P)$ on which the process $R_t^{q_1, q_2}$ is well defined. The information at time $t$ is given by the complete filtration $\mathcal{F}_t$ generated by $R_t^{q_1, q_2}$. The strategy $(q_1 t, q_2 t)$ is $\mathcal{F}_t$-predictable.

3 Optimal results for the compound Poisson model

In this section, we consider the optimization problem for the risk model (2.1). Throughout the paper, we assume that the reinsurance premium is calculated according to the variance principle. That is,

$$\delta(q_1, q_2) = (1 - q_1)a_1 + (1 - q_2)a_2 + \Lambda \tilde{h}(q_1, q_2).$$

(3.1)

Here, $\Lambda > 0$ is the safety loading of the reinsurer, and

$$\tilde{h}(q_1, q_2) = (1 - q_1)^2 \sigma_1^2 + (1 - q_2)^2 \sigma_2^2 + 2(1 - q_1)(1 - q_2)\lambda \mu_1 \mu_2.$$

To solve the equation

$$\sup_{q_1, q_2} \left\{ V_t + [rx + c - \delta(q_1, q_2)]V_x + \lambda_1 E[V(t, x - q_1 X) - V(t, x)] + \lambda_2 E[V(t, x - q_2 Y) - V(t, x)] + \lambda E[V(t, x - q_1 X - q_2 Y) - V(t, x)] \right\} = 0,$$

with the boundary condition $V(T, x) = u(x)$, inspired by Browne (1995), we try to fit a solution with the form

$$V(t, x) = -\frac{m}{\nu} \exp[-\nu x e^{r(T-t)} + h(T-t)],$$

(3.2)

where $h(\cdot)$ is a suitable function such that (3.2) is a solution to (2.6). The boundary condition $V(T, x) = u(x)$ implies that $h(0) = 0$. 

8
From (3.2), we get

\[
\begin{aligned}
V_1 &= V(t, x)[νxre^{r(T-t)} - h'(T-t)], \\
V_2 &= V(t, x)[-νe^{r(T-t)}], \\
V_{xx} &= V(t, x)[ν^2 e^{2r(T-t)}], \\
E[V(t, x - q_1 X) - V(t, x)] &= V(t, x)[M_X(νq_1 e^{r(T-t)}) - 1], \\
E[V(t, x - q_2 Y) - V(t, x)] &= V(t, x)[M_Y(νq_2 e^{r(T-t)}) - 1], \\
E[V(t, x - q_1 X - q_2 Y)] &= V(t, x)[M_X(νq_1 e^{r(T-t)}) M_Y(νq_2 e^{r(T-t)}) - 1].
\end{aligned}
\]  

(3.3)

Putting (3.3) into the equation (2.6) and rearranging terms yield

\[
\inf_{q_1, q_2} \{ -h'(T - t) - cνe^{r(T-t)} - λ_1 - λ_2 - λ + δ(q_1, q_2)νe^{r(T-t)} \}
+ λ_1 M_X(νq_1 e^{r(T-t)}) + λ_2 M_Y(νq_2 e^{r(T-t)})
+ λM_X(νq_1 e^{r(T-t)}) M_Y(νq_2 e^{r(T-t)}) \} = 0,
\]

(3.4)

for \( t < T \). Let

\[
\tilde{f}(q_1, q_2) = \delta(q_1, q_2)νe^{r(T-t)} + λ_1 M_X(νq_1 e^{r(T-t)})
+ λ_2 M_Y(νq_2 e^{r(T-t)}) + λM_X(νq_1 e^{r(T-t)}) M_Y(νq_2 e^{r(T-t)}).
\]

For any \( t \in [0, T] \), we have

\[
\begin{aligned}
\frac{∂\tilde{f}(q_1, q_2)}{∂q_1} &= (\frac{∂δ(q_1, q_2)}{∂q_1}) + \frac{∂f(q_1, q_2)}{∂q_1} (\lambda_1 + λM_Y(νq_2 e^{r(T-t)})) · νe^{r(T-t)}, \\
\frac{∂\tilde{f}(q_1, q_2)}{∂q_2} &= (\frac{∂δ(q_1, q_2)}{∂q_2}) + \frac{∂f(q_1, q_2)}{∂q_2} (\lambda_2 + λM_X(νq_1 e^{r(T-t)})) · νe^{r(T-t)}.
\end{aligned}
\]

Moreover, since

\[
δ(q_1, q_2) = (1 - q_1)a_1 + (1 - q_2)a_2 + Λh(q_1, q_2),
\]

we obtain

\[
\begin{aligned}
\frac{∂\tilde{f}(q_1, q_2)}{∂q_1} &= (-a_1 - Λ(2(1 - q_1)σ_1^2 + 2(1 - q_2)λμ_1μ_2)
+ M_X'(νq_1 e^{r(T-t)}) (λ_1 + λM_Y(νq_2 e^{r(T-t)})) · νe^{r(T-t)}, \\
\frac{∂\tilde{f}(q_1, q_2)}{∂q_2} &= (-a_2 - Λ(2(1 - q_2)σ_2^2 + 2(1 - q_1)λμ_1μ_2)
+ M_Y'(νq_2 e^{r(T-t)}) (λ_2 + λM_X(νq_1 e^{r(T-t)})) · νe^{r(T-t)}.
\end{aligned}
\]

9
Then, the Hessian matrix can be decomposed as

\[
\begin{aligned}
\frac{\partial^2 \tilde{f}(q_1, q_2)}{\partial q_1^2} &= M''_X(\nu q_1 e^{r(T-t)})(\lambda_1 + \lambda M_Y(\nu q_2 e^{r(T-t)})) \cdot \nu^2 e^{2r(T-t)} \\
    &\quad + 2\lambda \sigma_1^2 \cdot \nu e^{r(T-t)} > 0, \\
\frac{\partial^2 \tilde{f}(q_1, q_2)}{\partial q_2^2} &= M''_Y(\nu q_2 e^{r(T-t)})(\lambda_2 + \lambda M_X(\nu q_1 e^{r(T-t)})) \cdot \nu^2 e^{2r(T-t)} \\
    &\quad + 2\lambda \sigma_2^2 \cdot \nu e^{r(T-t)} > 0, \\
\frac{\partial^2 \tilde{f}(q_1, q_2)}{\partial q_1 \partial q_2} &= \frac{\partial^2 \tilde{f}(q_1, q_2)}{\partial q_2 \partial q_1} = 2\lambda \mu \nu e^{r(T-t)} \\
    &\quad + \lambda M'_X(\nu q_1 e^{r(T-t)}) \cdot M'_Y(\nu q_2 e^{r(T-t)}) \cdot \nu^2 e^{2r(T-t)}.
\end{aligned}
\]

Lemma 3.1. \( \tilde{f}(q_1, q_2) \) is a convex function with respect to \( q_1 \) and \( q_2 \).

**Proof:** To prove \( \tilde{f}(q_1, q_2) \) is a convex function with respect to \( q_1 \) and \( q_2 \), it is sufficient to prove that the Hessian matrix of \( \tilde{f}(q_1, q_2) \) is positive definite.

Let

\[
A = \begin{pmatrix}
\sigma_1^2 & \lambda \mu \mu_2 \\
\lambda \mu \mu_2 & \sigma_2^2
\end{pmatrix}, \quad
B = \begin{pmatrix}
\lambda_1 M''_X(\nu q_1 e^{r(T-t)}) & 0 \\
0 & \lambda_2 M''_Y(\nu q_2 e^{r(T-t)})
\end{pmatrix},
\]

and

\[
C = \begin{pmatrix}
M''_X(\nu q_1 e^{r(T-t)}) \cdot M_Y(\nu q_2 e^{r(T-t)}) & M'_X(\nu q_1 e^{r(T-t)}) \cdot M'_Y(\nu q_2 e^{r(T-t)}) \\
M'_X(\nu q_1 e^{r(T-t)}) \cdot M''_Y(\nu q_2 e^{r(T-t)}) & M''_Y(\nu q_2 e^{r(T-t)}) \cdot M_X(\nu q_1 e^{r(T-t)})
\end{pmatrix}.
\]

Then, the Hessian matrix can be decomposed as

\[
\begin{pmatrix}
\frac{\partial^2 \tilde{f}(q_1, q_2)}{\partial q_1^2} & \frac{\partial^2 \tilde{f}(q_1, q_2)}{\partial q_1 \partial q_2} \\
\frac{\partial^2 \tilde{f}(q_1, q_2)}{\partial q_2 \partial q_1} & \frac{\partial^2 \tilde{f}(q_1, q_2)}{\partial q_2^2}
\end{pmatrix} = A \cdot \nu e^{r(T-t)} + (B + \lambda \cdot C) \cdot \nu^2 e^{2r(T-t)}.
\]

It is easy to see that \( B \) is a nonnegative definite matrix. Furthermore, by the Cauchy–Schwarz inequality, it is not difficult to prove that \( A \) is a positive definite matrix, and that \( C \) is a nonnegative definite matrix. Thus, the Hessian matrix is a positive definite matrix. \( \square \)

Therefore, the minimizer \((q_1(T - t), q_2(T - t))\) of \( \tilde{f}(q_1, q_2) \) satisfies the following equations

\[
\begin{aligned}
a_1 + \Lambda(2(1 - q_1)\sigma_1^2 + 2(1 - q_2)\lambda \mu \mu_2) &= M'_X(\nu q_1 e^{r(T-t)})(\lambda_1 + \lambda M_Y(\nu q_2 e^{r(T-t)})), \\
a_2 + \Lambda(2(1 - q_2)\sigma_2^2 + 2(1 - q_1)\lambda \mu \mu_2) &= M'_Y(\nu q_2 e^{r(T-t)})(\lambda_2 + \lambda M_X(\nu q_1 e^{r(T-t)})).
\end{aligned}
\]

(3.5)

Moreover, we have
Lemma 3.2. For any \( t \in [0, T] \), if both \((q_{11}, q_{21})\) and \((q_{12}, q_{22})\) are the solution to the equations (3.5), then we have \( q_{11} = q_{12} \) and \( q_{21} = q_{22} \).

Proof: Assume that \( q_{11} \neq q_{12} \) or \( q_{21} \neq q_{22} \). By Taylor’s Theorem, we have

\[
\tilde{f}(q_{11}, q_{21}) = \tilde{f}(q_{12}, q_{22}) + \left( h \frac{\partial}{\partial q_1} + k \frac{\partial}{\partial q_2} \right) \tilde{f}(q_{12}, q_{22}) + \frac{1}{2!} \left( h \frac{\partial}{\partial q_1} + k \frac{\partial}{\partial q_2} \right)^2 \tilde{f}(q_{12} + \theta h, q_{22} + \theta k) = \tilde{f}(q_{12}, q_{22}) + \frac{1}{2} \Delta_1,
\]

where \( h = q_{11} - q_{12}, k = q_{21} - q_{22} \) and

\[
\Delta_1 = (h^2 \frac{\partial^2 \tilde{f}}{\partial q_1^2} + 2hk \frac{\partial^2 \tilde{f}}{\partial q_1 \partial q_2} + k^2 \frac{\partial^2 \tilde{f}}{\partial q_2^2}) \tilde{f}(q_{12} + \theta h, q_{22} + \theta k).
\]

From Lemma 3.1, we know that the Hessian matrix is a positive definite matrix, and thus

\[
\sqrt{\frac{\partial^2 \tilde{f}}{\partial q_1^2} \cdot \frac{\partial^2 \tilde{f}}{\partial q_2^2}} > |\frac{\partial^2 \tilde{f}}{\partial q_1 \partial q_2}|.
\]

Therefore, when \( h \neq 0 \) and \( k \neq 0 \),

\[
\Delta_1 \geq 2|hk| \sqrt{\frac{\partial^2 \tilde{f}}{\partial q_1^2} \cdot \frac{\partial^2 \tilde{f}}{\partial q_2^2}} + 2hk \frac{\partial^2 \tilde{f}}{\partial q_1 \partial q_2} > 0,
\]

which implies that

\[
\tilde{f}(q_{11}, q_{21}) = \tilde{f}(q_{12}, q_{22}) + \frac{1}{2} \Delta_1 > \tilde{f}(q_{12}, q_{22}). \tag{3.6}
\]

Along the same lines, one can obtain

\[
\tilde{f}(q_{12}, q_{22}) > \tilde{f}(q_{11}, q_{21}),
\]

which is contrary to (3.6).

For notational convenience, we rewrite equation (3.5) as

\[
\begin{align*}
\begin{cases}
\frac{\partial}{\partial t} a_1 + \Lambda(2(1 - \frac{n}{\nu} e^{-r(T-t)}) \sigma_1^2 + 2(1 - \frac{n}{\nu} e^{-r(T-t)}) \lambda \mu_1 \mu_2) &= M_X(n)(\lambda_1 + \lambda M_Y(m)), \\
\frac{\partial}{\partial t} a_2 + \Lambda(2(1 - \frac{n}{\nu} e^{-r(T-t)}) \sigma_2^2 + 2(1 - \frac{n}{\nu} e^{-r(T-t)}) \lambda \mu_1 \mu_2) &= M_Y(m)(\lambda_2 + \lambda M_X(n)),
\end{cases}
\end{align*}
\]

where \( n = \nu q_1 e^{r(T-t)} \) and \( m = \nu q_2 e^{r(T-t)} \). To prove the existence and uniqueness of the solution to (3.7), we need the following two more lemmas.
Lemma 3.3. For any $t \in [0, T]$, there is a unique positive solution to each of the following equations

\[
\lambda_1 M_Y(m) = \lambda_1 + 2\Lambda \sigma_1^2 + 2\Lambda \lambda_1 \mu_2 (1 - \frac{m}{\nu} e^{-r(T-t)}),
\]

(3.8)

and

\[
(\lambda_1 + \lambda) M'_X(n) = a_1 + 2\Lambda \lambda_1 \mu_2 + 2\Lambda \sigma_1^2 (1 - \frac{n}{\nu} e^{-r(T-t)}).
\]

(3.9)

Proof: We first discuss the equation (3.8). Let

\[
g_1(m) = \lambda_1 + 2\Lambda \sigma_1^2 + 2\Lambda \lambda_1 \mu_2 (1 - \frac{m}{\nu} e^{-r(T-t)}),
\]

and

\[
g_2(m) = \lambda_1 M_Y(m).
\]

Then, we have

\[
g_2(0) = \lambda_1,
\]

\[
g'_2(m) = E(Y e^{mY}) > 0,
\]

\[
g''_2(m) = E(Y^2 e^{mY}) > 0.
\]

That is, for any $t \in [0, T]$, $g_2(m)$ is an increasing convex function with $g_2(0) = \lambda_1$. Furthermore, $g_1(m)$ is a decreasing linear function with

\[
g_1(0) = \lambda_1 + 2\Lambda \sigma_1^2 + 2\Lambda \lambda_1 \mu_2 > g_2(0).
\]

Therefore, $g_1(m)$ and $g_2(m)$ have a unique point of intersection at some $m_1(t) > 0$. That is, equation (3.8) has a unique positive root.

We now consider the equation (3.9). Let

\[
g_3(n) = (\lambda_1 + \lambda) M'_X(n),
\]

and

\[
g_4(n) = a_1 + 2\Lambda \lambda_1 \mu_2 + 2\Lambda \sigma_1^2 (1 - \frac{n}{\nu} e^{-r(T-t)}).
\]

Then, we have

\[
g_3(0) = a_1,
\]

\[
g'_3(n) = E(X^2 e^{nX}) > 0,
\]

\[
g''_3(n) = E(X^3 e^{nX}) > 0.
\]

That is, for any $t \in [0, T]$, $g_3(n)$ is an increasing convex function with $g_3(0) = a_1$. Furthermore, $g_4(n)$ is a decreasing linear function with

\[
g_4(0) = a_1 + 2\Lambda \lambda_1 \mu_2 + 2\Lambda \sigma_1^2 > g_3(0).
\]
Therefore, \( g_3(n) \) and \( g_4(n) \) have a unique point of intersection at some \( n_1(t) > 0 \). That is, the equation (3.9) has a unique positive root.

\[ \square \]

**Lemma 3.4.** For any \( t \in [0, T] \), there is a unique positive solution to each of the following equations

\[
(\lambda_2 + \lambda)M'_Y(m) = a_2 + 2\lambda\mu_1\mu_2 + 2\lambda(1 - \frac{m}{\nu}e^{-r(T-t)})\sigma^2_2
\]

(3.10)

and

\[
\lambda\mu_2M_X(n) = \lambda\mu_2 + 2\lambda\sigma^2_2 + 2\lambda\mu_1\mu_2(1 - \frac{n}{\nu}e^{-r(T-t)}).
\]

(3.11)

**Proof:** Similar to the proof of Lemma 3.3, one can show that the equation (3.10) ((3.11)) has a unique positive root \( m_2(t) \) (\( n_2(t) \)).

The next lemma states the existence and uniqueness of the solution to the equation (3.7).

**Lemma 3.5.** Let \( m_1(t) \), \( n_1(t) \), \( m_2(t) \) and \( n_2(t) \) be the unique positive roots of the equations (3.8), (3.9), (3.10), and (3.11), respectively. If

\[
\begin{cases}
   m_1(t) > m_2(t), \\
   n_1(t) < n_2(t),
\end{cases}
\]

or

\[
\begin{cases}
   m_1(t) < m_2(t), \\
   n_1(t) > n_2(t),
\end{cases}
\]

hold for any \( t \in [0, T] \), then the equation (3.7) has a unique positive root \( (\bar{n}(T-t), \bar{m}(T-t)) \).

**Proof:** Let

\[
H_1(n, m) = a_1 + \Lambda(2(1 - \frac{n}{\nu}e^{-r(T-t)})\sigma^2_1 + 2(1 - \frac{m}{\nu}e^{-r(T-t)})\lambda\mu_1\mu_2)
- M'_X(n)(\lambda_1 + \lambda M_Y(m)),
\]

and

\[
H_2(n, m) = a_2 + \Lambda(2(1 - \frac{m}{\nu}e^{-r(T-t)})\sigma^2_2 + 2(1 - \frac{n}{\nu}e^{-r(T-t)})\lambda\mu_1\mu_2)
- M'_X(m)(\lambda_2 + \lambda M_X(n)).
\]

Assume that \( H_1(n, m) = 0 \) with \( m = f_1(n) \), and that \( H_2(n, m) = 0 \) with \( m = f_2(n) \). Differentiating both sides of \( H_1(n, m) = 0 \) with respect to \( n \) yields

\[
-2\Lambda(\sigma^2_1 + \mu_1\mu_2 f_1'(n))\frac{1}{\nu}e^{-r(T-t)} = \lambda f_1'(n)M'_Y(m)M'_X(n) + (\lambda M_Y(m) + \lambda_1)M'_X(n),
\]

(13)
and thus
\[ f'_1(n) = -\left(\frac{\lambda M_Y(n) + \lambda_1 M''_X(n) + 2\Delta \sigma^2 1_e^{-r(T-t)}}{\lambda M'_Y(m) M'_X(n) + 2\Delta \mu_1 \mu_2 1_{e^{-r(T-t)}}} \right) < 0. \]

Furthermore, it follows from Lemma 3.3 that the equations \( H_1(0, m) = 0 \) and \( H_1(n, 0) = 0 \) have unique positive solutions \( m_1(t) \) and \( n_1(t) \), respectively. Therefore, for any \( t \in [0, T] \), function \( f_1(n) \) is a decreasing function with
\[
\begin{cases}
  f_1(0) = m_1(t) > 0, \\
  f_1^{-1}(0) = n_1(t) > 0.
\end{cases}
\]

Along the same lines, from \( H_2(n, m) = 0 \), we obtain
\[ f'_2(n) = -\left(\frac{\lambda M'_Y(m) M'_X(n) + 2\Delta \mu_1 \mu_2 1_{e^{-r(T-t)}}}{\lambda M''_X(n) + \lambda_2 M''_Y(m) + 2\Delta \sigma^2 1_{e^{-r(T-t)}}} \right) < 0. \]

Using Lemma 3.4, one can show that the equations \( H_2(0, m) = 0 \) and \( H_2(n, 0) = 0 \) have unique positive solutions \( m_2(t) \) and \( n_2(t) \), respectively. Therefore, for any \( t \in [0, T] \), the function \( f_2(n) \) is also a decreasing function with
\[
\begin{cases}
  f_2(0) = m_2(t) > 0, \\
  f_2^{-1}(0) = n_2(t) > 0.
\end{cases}
\]

Note that, in the above equations, \( f_i^{-1} (i = 1, 2) \) is the inverse function of \( f_i \), \( M''_X(r) = E(X^2 e^{rX}) \), and \( M''_Y(r) = E(Y^2 e^{rY}) \).

Therefore, for any \( t \in [0, T] \), if the following inequalities
\[
\begin{cases}
  f_1(0) > f_2(0), \\
  f_1^{-1}(0) < f_2^{-1}(0),
\end{cases}
\]
or
\[
\begin{cases}
  f_1(0) < f_2(0), \\
  f_1^{-1}(0) < f_2^{-1}(0),
\end{cases}
\]
hold, the functions \( f_1(n) \) and \( f_2(n) \) have at least one point of intersection at some \( \tilde{n}(T - t) > 0 \).

Then, it follows from Lemma 3.2 that the equation (3.7) has a unique positive root \( (\tilde{n}(T - t), \tilde{m}(T - t)) \) with \( \tilde{m}(T - t) = f_1(\tilde{n}(T - t)) = f_2(\tilde{n}(T - t)) \).
From Lemma 3.5, we get $\nu q_1(T - t)e^{r(T - t)} = \bar{n}(T - t)$ and $\nu q_2(T - t)e^{r(T - t)} = \bar{m}(T - t)$, and thus

$$
\begin{cases}
q_1(T - t) = \frac{\bar{n}(T - t)}{\nu}e^{-r(T - t)}, \\
q_2(T - t) = \frac{\bar{m}(T - t)}{\nu}e^{-r(T - t)}.
\end{cases}
$$

(3.12)

Assume that $\hat{q}_1(T - t)$ and $\hat{q}_2(T - t)$ are the unique positive solutions to the following equations:

$$
a_1 + 2\Lambda(1 - q_1)^2 = M'_X(\nu q_1e^{r(T - t)})(\lambda_1 + \lambda M_Y(\nu e^{r(T - t)})),
$$

(3.13)

and

$$
a_2 + 2\Lambda(1 - q_2)^2 = M'_Y(\nu q_2e^{r(T - t)})(\lambda_2 + \lambda M_X(\nu e^{r(T - t)})),
$$

(3.14)

respectively. Let $t_1(t_{01})$ and $t_2(t_{02})$ be the time points at which $q_1(T - t) = 1$ ($\hat{q}_1(T - t) = 1$) and $q_2(T - t) = 1$ ($\hat{q}_2(T - t) = 1$), respectively. By the convexity of the function $\tilde{f}$, we derive the optimal reinsurance strategy

$$
(q_1^*(T - t), q_2^*(T - t)) = \begin{cases}
(q_1(T - t), q_2(T - t)), & 0 < t < t_2, \\
(\hat{q}_1(T - t), 1), & t_2 \leq t < t_{01}, \\
(1, 1), & t \geq t_{01},
\end{cases}
$$

when $t_1 > t_2$, and

$$
(q_1^*(T - t), q_2^*(T - t)) = \begin{cases}
(q_1(T - t), q_2(T - t)), & 0 < t < t_1, \\
(1, \hat{q}_2(T - t)), & t_1 \leq t < t_{02}, \\
(1, 1), & t \geq t_{02},
\end{cases}
$$

when $t_1 \leq t_2$.

Putting the optimal reinsurance strategies $(q_1^*(T - t), q_2^*(T - t))$ back into (3.4) yields

$$
h_1(T - t) = -\frac{1}{r}\alpha\nu(e^{r(T - t)} - 1) - (\lambda_1 + \lambda_2 + \lambda)(T - t) + \int_0^{T - t} K(s)ds,
$$

(3.15)

where

$$
K(s) = \delta(q_1^*(s), q_2^*(s))\nu e^{r\nu s} + \lambda_1 M_X(\nu q_1^*(s)e^s) + (\lambda_2 + \lambda M_X(\nu q_1^*(s)e^s))M_Y(\nu q_2^*(s)e^s).
$$

To summarize, we have
Theorem 3.1. Let \((q_1(T - t), q_2(T - t))\) be given in the equation (3.12), and \(\hat{q}_1(T - t)\) and \(\hat{q}_2(T - t)\) be the unique positive solution to the equations (3.13) and (3.14), respectively. Then, for any \(t \in [0, T]\), the optimal reinsurance strategy for the risk model (2.1) is

\[
(q_1^*(T - t), q_2^*(T - t)) = \begin{cases} 
(q_1(T - t), q_2(T - t)), & 0 < t < t_2, \\
(\hat{q}_1(T - t), 1), & t_2 \leq t < t_{01}, \\
(1, 1), & t \geq t_{01},
\end{cases}
\]

for \(t_1 > t_2\), and

\[
(q_1^*(T - t), q_2^*(T - t)) = \begin{cases} 
(q_1(T - t), q_2(T - t)), & 0 < t < t_1, \\
(1, \hat{q}_2(T - t)), & t_1 \leq t < t_{02}, \\
(1, 1), & t \geq t_{02},
\end{cases}
\]

for \(t_1 \leq t_2\). Moreover, the value function is given by

\[
V(t, x) = -\frac{m}{\nu} \exp\{-\nu xe^{r(T-t)} + h_1(T - t)\},
\]

where \(h_1(T - t)\) is defined in (3.15).

Remark 3.1. When the two compound Poisson processes \(S_1(t)\) and \(S_2(t)\) have the same distribution, i.e., \(\lambda_1 = \lambda_2\), \(\mu_1 = \mu_2\), and \(\sigma_1 = \sigma_2\), it is not difficult to see from (3.8)-(3.11) that \(m_1(t) = n_2(t)\) and \(n_1(t) = m_2(t)\). By symmetry, we have \(\bar{m}(T - t) = \bar{n}(T - t)\), and therefore \(q_1^*(T - t) = q_2^*(T - t)\).

4 Optimal results for the diffusion model

In this section, we discuss the optimization problem for the diffusion risk model. The surplus process of the risk model (2.2) evolves as

\[
d\bar{R}_t^{q_1,q_2} = \left[ r\bar{R}_t^{q_1,q_2} + (c - \delta(q_1, q_2)) - q_1a_1 - q_2a_2 \right] dt \\
+ \sqrt{\sigma_1^2 q_1^2 + \sigma_2^2 q_2^2 + 2q_1 q_2 \lambda \mu_1 \mu_2} dB_t,
\]

and the corresponding HJB equation is

\[
\sup_{q_1,q_2} \left\{ V_t + \left[ rx + c - \delta(q_1, q_2) - q_1a_1 - q_2a_2 \right] V_x \\
+ \frac{1}{2} \left( \sigma_1^2 q_1^2 + \sigma_2^2 q_2^2 + 2q_1 q_2 \lambda \mu_1 \mu_2 \right) V_{xx} \right\} = 0
\]

(4.1)
for \( t < T \), with the boundary condition \( V(T, x) = u(x) \).

To derive the optimal reinsurance strategy which satisfies the HJB equation (4.1), we again try to use a solution with the form (3.2). After substituting (3.3) into (4.1) and some algebraic manipulation, we obtain

\[
\inf_{q_1, q_2} \left\{ -h'(T - t) - [c - \delta(q_1, q_2) - q_1a_1 - q_2a_2]v e^{r(T - t)} + \frac{1}{2}(\sigma_1^2 q_1^2 + \sigma_2^2 q_2^2 + 2q_1q_2\lambda\mu_1\mu_2)\nu^2 e^{2r(T - t)} \right\} = 0.
\]

(4.2)

Let

\[
\tilde{f}_1(q_1, q_2) = (\delta(q_1, q_2) + q_1a_1 + q_2a_2)\nu e^{r(T - t)} + \frac{1}{2}(\sigma_1^2 q_1^2 + \sigma_2^2 q_2^2 + 2q_1q_2\lambda\mu_1\mu_2)\nu^2 e^{2r(T - t)},
\]

Then, for any \( t \in [0, T] \), we get

\[
\begin{align*}
\frac{\partial \tilde{f}_1(q_1, q_2)}{\partial q_1} & = -(2\Lambda((1 - q_1)\sigma_1^2 + (1 - q_2)\lambda\mu_1\mu_2))\nu e^{r(T - t)} + (q_1\sigma_1^2 + \lambda q_2\mu_1\mu_2)\nu^2 e^{2r(T - t)}, \\
\frac{\partial^2 \tilde{f}_1(q_1, q_2)}{\partial q_1^2} & = 2\Lambda\sigma_1^2\nu e^{r(T - t)} + \sigma_1^2\nu^2 e^{2r(T - t)} > 0, \\
\frac{\partial \tilde{f}_1(q_1, q_2)}{\partial q_2} & = -(2\Lambda((1 - q_2)\sigma_2^2 + (1 - q_1)\lambda\mu_1\mu_2))\nu e^{r(T - t)} + (q_2\sigma_2^2 + \lambda q_1\mu_1\mu_2)\nu^2 e^{2r(T - t)}, \\
\frac{\partial^2 \tilde{f}_1(q_1, q_2)}{\partial q_2^2} & = 2\Lambda\sigma_2^2\nu e^{r(T - t)} + \sigma_2^2\nu^2 e^{2r(T - t)} > 0, \\
\frac{\partial^2 \tilde{f}_1(q_1, q_2)}{\partial q_1 \partial q_2} & = 2\Lambda\mu_1\mu_2\nu e^{r(T - t)} + \lambda \mu_1\mu_2\nu^2 e^{2r(T - t)}.
\end{align*}
\]

The Hessian matrix in this case is given by \( A \cdot (2\Lambda + \nu e^{r(T - t)}) \), which is also a positive definite matrix. Thus, \( \tilde{f}_1(q_1, q_2) \) is a convex function with respect to \( q_1 \) and \( q_2 \). Therefore, the minimizer \((\tilde{q}_1(T - t), \tilde{q}_2(T - t))\) of \( \tilde{f}_1(q_1, q_2) \) satisfies the following equations

\[
\begin{align*}
-(2\Lambda((1 - q_1)\sigma_1^2 + (1 - q_2)\lambda\mu_1\mu_2)) + (q_1\sigma_1^2 + \lambda q_2\mu_1\mu_2)\nu e^{r(T - t)} & = 0, \\
-(2\Lambda((1 - q_2)\sigma_2^2 + (1 - q_1)\lambda\mu_1\mu_2)) + (q_2\sigma_2^2 + \lambda q_1\mu_1\mu_2)\nu e^{r(T - t)} & = 0,
\end{align*}
\]

which can be rewritten as

\[
\begin{align*}
q_1\sigma_1^2 + \lambda q_2\mu_1\mu_2 & = \frac{2\Lambda\sigma_1^2 + 2\Lambda\lambda\mu_1\mu_2}{2\Lambda + \nu e^{r(T - t)}}, \\
q_2\sigma_2^2 + \lambda q_1\mu_1\mu_2 & = \frac{2\Lambda\sigma_2^2 + 2\Lambda\lambda\mu_1\mu_2}{2\Lambda + \nu e^{r(T - t)}}.
\end{align*}
\]
Then, it is not difficult to derive the following solution

\[
\begin{aligned}
\bar{q}_1(T - t) &= \frac{2\Lambda}{2\Lambda + \nu e^{r(T - t)}}, \\
\bar{q}_2(T - t) &= \frac{2\Lambda}{2\Lambda + \nu e^{r(T - t)}}.
\end{aligned}
\]

Since

\[
\frac{2\Lambda}{2\Lambda + \nu e^{r(T - t)}} \in (0, 1),
\]

we obtain the optimal reinsurance strategy

\[
q^*_1t = q^*_2t = \frac{2\Lambda}{2\Lambda + \nu e^{r(T - t)}}.
\]

Putting \(q^*_1t = q^*_2t = \bar{q}_1(T - t)\) into (4.2) yields

\[
h_3(T - t) = \frac{1}{r}(a_0 - c)\nu(e^{r(T - t)} - 1) + \int_0^{T - t} K_1(s)ds,
\]

with

\[
K_1(s) = \Lambda(1 - \bar{q}_1(s))\sigma^2_0 e^{rs} + \frac{1}{2} \bar{q}_1(s)^2 \sigma^2_0 \nu^2 e^{2rs}.
\]

Finally, we summarize the result of this subsection in the following theorem.

**Theorem 4.1.** For any \(t \in [0, T]\), the optimal reinsurance strategy for the risk model (2.2) is

\[
q^*_1t = q^*_2t = \frac{2\Lambda}{2\Lambda + \nu e^{r(T - t)}},
\]

and the value function is

\[
V(t, x) = -\frac{m}{\nu} \exp\{-\nu xe^{r(T - t)} + h_3(T - t)\}.
\]

where \(h_3(T - t)\) is defined in (4.3).

**Remark 4.1.** From (4.4), we see that the optimal reinsurance strategy in this case is the same as the one in Theorems 4.1 and 5.2 of Liang et al. (2011).

**Remark 4.2.** The optimal reinsurance strategies for the diffusion model depends only on the safety loading \(\Lambda\), time \(T - t\), and interest rate \(r\). That is, the claim size distributions as well as the counting processes have no effect on the optimal reinsurance strategy. However, from the numerical results shown in Section 5, the optimal results for the compound Poisson model depend not only on the safety loading \(\Lambda\), time \(T - t\), and interest rate \(r\), but also on the claim size distributions and the counting processes.
5 Numerical examples

In this section, we assume that the claim sizes $X_i$ and $Y_i$ are exponentially distributed with parameters $\alpha_1$ and $\alpha_2$, respectively. Then, we have

\[
\begin{align*}
M_X(\nu q_1 e^{r(T-t)}) &= \frac{\alpha_1}{\alpha_1 - \nu q_1 e^{r(T-t)}}, \\
M_Y(\nu q_2 e^{r(T-t)}) &= \frac{\alpha_2}{\alpha_2 - \nu q_2 e^{r(T-t)}}.
\end{align*}
\]

The minimizer $(q_1(T-t), q_2(T-t))$ of (3.3) satisfies the following equations

\[
\begin{align*}
a_1 + \Lambda (2(1-q_1)\sigma_1^2 + 2(1-q_2)\lambda \mu_1 \mu_2) &= \frac{\alpha_1}{(\alpha_1 - \nu q_1 e^{r(T-t)})^2} (\lambda_1 + \frac{\lambda \alpha_2}{\alpha_2 - \nu q_2 e^{r(T-t)})}, \\
a_2 + \Lambda (2(1-q_2)\sigma_2^2 + 2(1-q_1)\lambda \mu_1 \mu_2) &= \frac{\alpha_2}{(\alpha_2 - \nu q_2 e^{r(T-t)})^2} (\lambda_2 + \frac{\lambda \alpha_1}{\alpha_1 - \nu q_1 e^{r(T-t)})},
\end{align*}
\]

with $\mu_1 = 1/\alpha_1$, $\mu_2 = 1/\alpha_2$, $\sigma_1^2 = 2(\lambda_1 + \lambda)/\alpha_1^2$ and $\sigma_2^2 = 2(\lambda_2 + \lambda)/\alpha_2^2$.

Example 5.1. In this example, we set $\lambda_1 = 3$, $r = 0.05$, $T = 10$, $\lambda_2 = 4$, $\Lambda = 2$, $\lambda = 2$, $\alpha_1 = 2$, and $\alpha_2 = 3$. The results are shown in Tables 5.1, 5.2 and 5.3.

From Table 5.1 with \( \nu = 0.5 \) and \( \Lambda = 2 \), we see that the optimal reinsurance strategies increase as \( t \) increases. Note that \( \nu \) is the constant absolute risk aversion parameter of the utility function, a large value of \( \nu \) means more risk averse. In Table 5.2 with \( t = 5 \) and \( \Lambda = 2 \), we observe that the optimal reinsurance strategies decrease as \( \nu \) increases. This implies that if the decision maker is more risk averse, a larger portion of the underlying risk will be transferred to a reinsurer. Besides, the results in Table 5.3 with \( t = 5 \) and \( \nu = 0.5 \) indicate that the optimal reinsurance strategies do not necessarily increase as the value of \( \Lambda \) increases.

**Example 5.2.** In this example, we put \( \lambda_1 = 3, \ r = 0.05, \ T = 10, \ \lambda_2 = 4, \ \nu = 0.5, \ \lambda = 2, \ t = 5, \) and \( \Lambda = 2 \). Tables 5.4 and 5.5 present the impact of \( \alpha_1 \) and \( \alpha_2 \) on the optimal reinsurance strategies.

</table>

We see from Table 5.4 with \( \alpha_2 = 3 \) and Table 5.5 with \( \alpha_1 = 2 \) that a greater value of \( \alpha_i \) yields a greater value of the optimal reinsurance strategy \( q_i^* \). However, \( q_1^* (q_2^*) \) does not necessarily increase as the value of \( \alpha_2 (\alpha_1) \) increases. We can also observe from Tables 5.4 and 5.5 that the value of \( q_1^* \) is always smaller than the value of \( q_2^* \) when the inequality \( \alpha_1 < \alpha_2 \) holds, and vice versa. This implies that the values of the optimal reinsurance strategies are more sensitive to the change in the claim size distributions than to the change in the counting processes (see also Table 5.7).
Example 5.3. For \( r = 0.05, T = 10, \nu = 0.5, \Lambda = 2, t = 5, \alpha_1 = 2, \) and \( \alpha_2 = 3, \) the optimal results are displayed in Tables 5.6 and 5.7.

</table>

Table 5.6 with \( \lambda_1 = 3 \) and \( \lambda_2 = 4 \) shows that the optimal reinsurance strategies decrease while the value of \( \lambda \) increases. This is consistent with the fact that the insurer would rather retain a less share of each claim when the expected claim number becomes larger. On the other hand, the numerical values in Table 5.7 with \( \lambda = 2 \) and \( \lambda_1 = 3 \) indicate that a greater value of \( \lambda_2 \) yields a greater value of \( q_2^* \) but a smaller value of \( q_1^* \). Along the same lines, one can numerically show that a greater value of \( \lambda_1 \) yields a greater value of \( q_1^* \) but a smaller value of \( q_2^* \). Finally, Tables 5.6 and 5.7 also exhibit that the changes in the optimal reinsurance strategies are small. These suggest that the optimal reinsurance strategies are kind of insensitive to the change in the counting processes. \( \square \)

6 Conclusion

We first recap the main results of the paper. From an insurer’s point of view, we consider the optimal proportional reinsurance strategy in a risk model with two dependent classes of insurance business, where the two claim number processes are correlated. By a nonstandard approach, we investigate the existence and uniqueness of the optimal reinsurance strategy. Under the criterion of maximizing the expected exponential utility together with the variance premium principle, closed-form expressions for the optimal strategy and value function are given not only for the compound
Poisson risk model but also for the diffusion model. Furthermore, we find that the optimal reinsurance strategies in the diffusion risk model only depend on the safety loading, time, and interest rate. However, from the numerical examples, we see that the optimal results for the compound Poisson model depend not only on the safety loading, time, and interest rate, but also on the claim size distributions and the counting processes.

In this paper, we may extend our work to the case of Centeno (2005) in which different safety loadings are used for the two classes of insurance business. In this case, the reinsurance premium rate becomes

\[
\delta(q_1, q_2) = (1 - q_1)a_1 + \Lambda_1 (1 - q_1)^2 \sigma_1^2 + (1 - q_2)a_2 + \Lambda_2 (1 - q_2)^2 \sigma_2^2. \tag{6.1}
\]

Since the dependence between \(S_1(t) (\hat{S}_1(t))\) and \(S_2(t) (\hat{S}_2(t))\) is not considered in (6.1), it is simpler than (3.1) and results in a simpler version of the equation (3.5). Moreover, following the ideas and steps in Section 3, one can investigate the existence and uniqueness of the optimal reinsurance strategies, and derive closed form expressions for the optimal results for the compound Poisson risk model. On the other hand, it can be shown that the optimal reinsurance strategies for the diffusion risk model are given by

\[
\begin{align*}
q_1^* &= \frac{2\Lambda_1 \sigma_1^2 \sigma_2^2 (2\Lambda_2 + \nu e^{(T-t)}) - 2\Lambda_2 \sigma_2^2 \lambda_1 \mu_2 \nu e^{(T-t)} - \lambda^2 \mu_1^2 \mu_2^2 \nu^2 e^{2(T-t)}}{\sigma_1^2 \sigma_2^2 (2\Lambda_2 + \nu e^{(T-t)}) (2\Lambda_1 + \nu e^{(T-t)}) - \lambda^2 \mu_1^2 \mu_2^2 \nu^2 e^{2(T-t)}}, \\
q_2^* &= \frac{2\Lambda_2 \sigma_1^2 \sigma_2^2 (2\Lambda_1 + \nu e^{(T-t)}) - 2\Lambda_1 \sigma_1^2 \lambda_1 \mu_2 \nu e^{(T-t)} - \lambda^2 \mu_1^2 \mu_2^2 \nu^2 e^{2(T-t)}}{\sigma_1^2 \sigma_2^2 (2\Lambda_2 + \nu e^{(T-t)}) (2\Lambda_1 + \nu e^{(T-t)}) - \lambda^2 \mu_1^2 \mu_2^2 \nu^2 e^{2(T-t)}}.
\end{align*}
\]

It is obvious that the optimal reinsurance strategies are different in the diffusion risk model. They depend not only on the safety loading, time, and interest rate, but also on the claim size distributions and the counting processes.

Although the literature on optimal reinsurance is increasing rapidly, very few of these contributions deal with the problem in relation to dependent risks. Therefore, there are still some interesting problems in this direction that can be further studied. For example, one may consider the optimal reinsurance with dependent risks under the partial information, multi-criteria, or stochastic differential games. Moreover, the optimal reinsurance problem with expected utility under additional constraints on the probability of ruin is a very challenging problem, especially for risk processes with jumps.
