Optimal dividend and reinsurance in the presence of two reinsurers

Mi Chen and Kam Chuen Yuen

Abstract: In this paper, the optimal dividend (subject to transaction costs) and reinsurance (with two reinsurers) problem is studied in the limit diffusion setting. It is assumed that transaction costs and taxes are required when dividends occur, and that the premiums charged by two reinsurers are calculated according to the exponential premium principle with different parameters, which makes the stochastic control problem nonlinear. The objective of the insurer is to determine the optimal reinsurance and dividend policy so as to maximize the expected discounted dividends until ruin. The problem is formulated as a mixed classical-impulse stochastic control problem. Explicit expressions for the value function and the corresponding optimal strategy are obtained. Finally, a numerical example is presented to illustrate the impact of the parameters associated with the two reinsurers’ premium principle on the optimal reinsurance strategy.

Keywords: dividend; reinsurance; transaction costs; exponential premium principle; optimal reinsurance with two reinsurers

1. Introduction

In the actuarial literature, insurance risk model with dividend payments was first considered by de Finetti [7]. In his paper, the optimal expected discounted sum of dividend payments until the time of ruin was studied in a simple discrete time model. Since then, many researchers carried out similar analysis for various risk models with more general and realistic features. For example, optimal dividend problems with transaction costs and controlled risk exposure can be found in Cadenillas et al. [3], He and Liang [11, 12], Løkka and Zervos [15], Bái et al. [2], Meng and Siu [16, 17], Scheer and Schmidli [21], Peng et al. [20] and Guan and Liang [9].

In most of the literature, premium is assumed to be calculated via the expected value principle for mathematical convenience. However, it is natural to argue that two risks with same mean may look very different from each other, and hence the associated premiums should also be different. The exponential premium principle, which is the so-called zero utility principle, plays an important role in insurance mathematics and
actuarial practice. It has many nice properties, including additivity with respect to independent risks. It is also widely used in mathematical finance to price various insurance products in the market. We refer the readers to Young and Zariphopoulou [26], Young [25], Moore and Young [18] and Musiela and Zariphopoulou [19]. For the optimal reinsurance problems under other premium principles, one can see Schmidli [22], Young [24], Kaluszka [13, 14], Zhou and Yuen [27] and Yao et al. [23].

In practice, insurance companies often purchase reinsurance to reduce the risk of their insurance portfolios. For simplicity, it is usually assumed in the literature that an insurer can only buy reinsurance from one reinsurer. However, it is commonly seen that some insurance company would like to diversify its risk by purchasing reinsurance from multiple reinsurance companies who may have different risk attitudes. Thus, it is meaningful to study the optimal reinsurance models with multiple reinsurers. Recently, optimal reinsurance problems with multiple reinsurers under the criterion of minimizing value at risk (VaR) or conditional value at risk (CVaR) of the insurer’s total risk exposure were studied by Asimit et al. [1] and Chi and Meng [5].

Under the exponential premium principle, the optimal dividend problem without transaction costs is investigated in Chen et al. [4], where only one reinsurer is considered. In this paper, we study the optimal dividend problem subject to transaction costs and optimal reinsurance with two reinsurers in the framework of diffusion model. We assume that the premiums charged by the two reinsurers are calculated according to the exponential premium principle with different parameters, which is closely related to a kind of nonlinear classical-impulse stochastic control problem. Under the exponential premium principle, the risk control becomes nonlinear which makes the problem more complicated than that under the expected value premium principle. In view of the complexity, we consider proportional reinsurance only in our study. Our objective is to maximize the expected discounted dividends until ruin. Explicit expressions for the value function and the corresponding optimal strategies are derived.

The rest of this paper is organized as follows. In Section 2, we present the mathematical formulation of the model with proportional reinsurance and dividend payments under the exponential premium principle. In Section 3, we give the quasi-variational inequalities (QVI) and the verification theorem of the problem. In Section 4, we give the solution to the optimization problem. We then give some comments in Section 5, and provide a numerical example in Section 6.
2. The Model

In this paper, all stochastic quantities are defined on a large enough complete probability space \((\Omega, \mathcal{F}, \mathcal{F}_t, \mathbf{P})\), where the filtration \(\mathcal{F}_t\) represents the information available at time \(t\) and any decision made is based on this information.

Our results will be formulated within the controlled diffusion model. But we start with the classical Cramér-Lundberg model, in which the surplus process of an insurer is given by

\[ U_t = x + ct - \sum_{i=1}^{N_t} Y_i, \]

where \( x \geq 0 \) is the initial surplus, \( c > 0 \) is the premium rate, \( \{N(t), t \geq 0\} \) is a homogeneous Poisson process with intensity \( \lambda \), and \( \{Y_i, i \geq 1\} \) is a sequence of positive i.i.d. random variables with common distribution \( F(y) \).

We denote by \( \mu_1 = E(Y_i) \) its mean and by \( M_{Y}(r) = E(e^{rY}) \) its moment generating function. It is usually assumed that the Cramér-Lundberg conditions hold, i.e., there exists \( 0 < r_{\infty} < \infty \) such that \( M_{Y}(r) < 1 \) if \( r < r_{\infty} \) and that \( \lim_{r \to r_{\infty}} M_Y(r) = +\infty \).

Here, we assume that the insurer is allowed to reduce the risk by purchasing proportional reinsurance with two reinsurers. Specifically, for a claim \( Y \) occurring at time \( t \), the first reinsurer pays \( (1 - b_t)Y \), the second reinsurer pays \( (1 - u_t)b_tY \), and the insurer itself pays \( u_t b_t Y \). We denote by \( C(b_t, u_t) \) the net income rate of the insurer at time \( t \). Then the surplus process in the presence of proportional reinsurance (for fixed \( b \) and \( u \)) can be written as

\[ U_t^{b,u} = x + C(b, u)t - \sum_{i=1}^{N_t} ubY_i. \]  \(\text{(2.1)}\)

It is well known that (2.1) can be approximated by a pure diffusion model \( X_t^{b,u} \) with the same drift and volatility. Specifically, if \( b \) and \( u \) change with time and are stochastic, then the controlled surplus process \( X_t^{b,u} \) with the strategy \( (b_t, u_t) \) satisfies

\[ dX_t^{b,u} = [C(b_t, u_t) - \lambda u_t b_t \mu_1]dt + \sqrt{\lambda \mu_2 u_t b_t}dW_t, \]  \(\text{(2.2)}\)

with \( X_0^{b,u} = x \), where \( \{W_t, t \geq 0\} \) is a standard Brownian motion, and \( \mu_1, \mu_2 \) are the first two moments of \( Y_i \).

In addition to purchasing proportional reinsurance, the insurance portfolio pays dividends to its shareholders under some dividend strategy. Here, we take into account a fixed transaction cost \( K > 0 \) and a tax rate \( 1 - k \) \((0 < k < 1)\) which are incurred each time the dividend is paid out. Since every dividend results in a fixed transaction cost \( K > 0 \), the insurance company should not pay out dividends continuously. Instead, it should pay dividends at some discrete time points. Then, a strategy is described by

\[ \alpha = (b_t; u_t; \tau_1, \tau_2, \ldots, \tau_n, \ldots; \xi_1, \xi_2, \ldots, \xi_n, \ldots) \]
where \( \tau_n \) and \( \xi_n \) denote the times and amounts of dividends. For a strategy \( \alpha \), we denote by \( X_t^\alpha \) the associated surplus process whose dynamics is given by

\[
X_t^\alpha = x + \int_0^t \mu(b_s, u_s) ds + \int_0^t \sqrt{\lambda \mu^2 b_s u_s} dW_s - \sum_{n=1}^\infty I_{(\tau_n < t)} \xi_n,
\]

where

\[
\mu(b_s, u_s) = C(b_s, u_s) - \lambda u_s b_s \mu_1.
\]

The ruin time of the controlled process \( X_t^\alpha \) is then defined as

\[
\tau^\alpha = \inf\{t \geq 0 : X_t^\alpha < 0\}.
\]

**Definition 2.1.** A strategy \( \alpha \) is said to be admissible if

(i) \( b_t \) and \( u_t \) are \( \{F_t\}_{t \geq 0} \)-adapted processes with \( 0 \leq b_t \leq 1, 0 \leq u_t \leq 1 \) for all \( t \geq 0 \).

(ii) \( \tau_n \) is a stopping time with respect to \( \{F_t\}_{t \geq 0} \) and \( 0 \leq \tau_1 < \tau_2 < \cdots < \tau_n < \cdots \) a.s.

(iii) \( \xi_n \) is measurable with respect to \( F_{\tau_n} \) and \( 0 < \xi_n \leq X_{\tau_n}^\alpha, n = 1, 2, \ldots \).

(iv) \( P(\lim_{n \to \infty} \tau_n \leq T) = 0 \), for all \( T \geq 0 \).

The set of all admissible control strategies is denoted by \( \Pi \). For a given admissible strategy \( \alpha \), we define the return function as

\[
V_\alpha(x) = E\left[ \sum_{n=1}^\infty e^{-\delta \tau_n} (k \xi_n - K) I_{\{\tau_n < \tau^\alpha\}} | X_0 = x \right] = E_x\left[ \sum_{n=1}^\infty e^{-\delta \tau_n} (k \xi_n - K) I_{\{\tau_n < \tau^\alpha\}} \right],
\]

which represents the expected total discounted dividends received by the shareholders until the ruin time when the initial surplus is \( x \), where \( \delta > 0 \) is a priori given discount factor. The objective is to find the optimal return function (or value function), which is defined as

\[
V(x) = \sup_{\alpha \in \Pi} V_\alpha(x), \tag{2.5}
\]

and to find the optimal strategy \( \alpha^* \) such that \( V(x) = V_{\alpha^*}(x) \) for all \( x \geq 0 \).

### 3. QVI and verification theorem

For a function \( \phi : [0, \infty) \to [0, \infty) \), we define the maximum operator \( \mathcal{M} \) as

\[
\mathcal{M}\phi(x) := \sup\{\phi(x - \eta) + k\eta - K : 0 < \eta \leq x\},
\]

and the operator \( \mathcal{L}^{b,u} \) as

\[
\mathcal{L}^{b,u}\phi(x) := \frac{1}{2}\lambda \mu^2 b^2 u^2 \phi''(x) + \mu(b, u) \phi'(x).
\]
Remark 3.1. For the value function $V(x)$, it is easy to see that $\mathcal{M}V(x) \leq V(x)$.

If the value function of (2.5) is sufficiently smooth, then by standard arguments in stochastic control (see, e.g., Fleming and Soner [8]), the corresponding QVI is given by

$$\max \left\{ \max_{0 \leq b \leq 1, 0 \leq u \leq 1} \mathcal{L}^{b,u}V(x) - \delta V(x), \mathcal{M}V(x) - V(x) \right\} = 0, \quad x > 0,$$

with boundary condition $V(0) = 0$. Given a solution $v(x)$ to (3.1), we can construct the following Markov control strategy.

Definition 3.1. The strategy $\alpha^v = (b^v_t, u^v_t; \tau^v_1, \tau^v_2, \ldots, \tau^v_n; \xi^v_1, \xi^v_2, \ldots, \xi^v_n, \cdots)$ is called the QVI strategy associated with $v$ if the associated process $X^v$ given by (2.3) with $x \geq 0$ satisfies

$$(b^v_t, u^v_t) = \arg \max_{0 \leq b \leq 1, 0 \leq u \leq 1} \mathcal{L}^{b,u}v(X^v_t) \text{ on } \{v(X^v_t) > \mathcal{M}v(X^v_t)\},$$

$$\tau^v_t = \inf \{t \geq 0 : v(X^v_t) = \mathcal{M}v(X^v_t)\},$$

$$\xi^v_t = \arg \sup_{0 < \eta \leq X^v_{\tau^v_t}} \{v(X^v_{\tau^v_t} - \eta) + k\eta - K\},$$

and for every $n \geq 2$,

$$\tau^v_n = \inf \{t > \tau^v_{n-1} : v(X^v_t) = \mathcal{M}v(X^v_t)\},$$

$$\xi^v_n = \arg \sup_{0 < \eta \leq X^v_{\tau^v_n}} \{v(X^v_{\tau^v_n} - \eta) + k\eta - K\}.$$

Throughout this paper, we assume that the reinsurance premium is calculated according to the exponential premium principle. That is, for a risk $U$, the amount of premium $\pi_a(U)$ is determined by

$$\pi_a(U) = \frac{1}{a} \ln E(e^{aU}),$$

where the constant $a > 0$ measures the risk aversion of the reinsurance company. We allow the two reinsurers to have different risk aversion, and the parameters for them are $a_1$ and $a_2$, respectively. Then $\mu(b_t, u_t)$ defined in (2.4) becomes

$$\mu(b_t, u_t) = c - \frac{\lambda}{a_1} (M_Y(a_1(1 - b_t)) - 1) - \frac{\lambda}{a_2} (M_Y(a_2(1 - u_t)b_t) - 1) - \lambda u_t b_t \mu_1. \quad (3.2)$$

Remark 3.2. For the expected premium principle, diversifying between different reinsurers is never optimal for the insurer. The reinsurer with the smallest safety loading will always be the one providing the cheapest insurance, and the insurer will
always buy reinsurance from this reinsurer. However, for the exponential premium principle, the situation is completely different. For example, for a risk $X$, it is easy to see that $\pi_a(X) \geq 2\pi_a\left(\frac{X}{2}\right)$, which means that diversifying the risk between two reinsurers with the same parameter $a$ is always better than sticking with one of them only. Besides, for two reinsurers with parameters $a_1$ and $a_2$ ($a_1 < a_2$), it is still possible that $\pi_{a_1}(X) > \pi_{a_1}(bX) + \pi_{a_2}((1-b)X)$ for some $0 < b < 1$. In this case, both reinsurers play a role in the optimal reinsurance design.

**Remark 3.3.** (i) Let $\mu(b, u)$ be the function defined in (3.2). Note that
\[
\max_{0 \leq b \leq 1} \mu(b, 0) = \mu\left(\frac{a_1}{a_1 + a_2}, 0\right) = c - \lambda \frac{a_1 + a_2}{a_1 a_2} \left(M_Y\left(\frac{a_1 a_2}{a_1 + a_2}\right) - 1\right).
\]
If
\[
c > \lambda \frac{a_1 + a_2}{a_1 a_2} \left(M_Y\left(\frac{a_1 a_2}{a_1 + a_2}\right) - 1\right), \quad \text{i.e.,} \quad \mu\left(\frac{a_1}{a_1 + a_2}, 0\right) > 0,
\]
then we can choose $b = a_1 / (a_1 + a_2)$ and $u = 0$ in (2.2) such that $X_t = x + \mu(a_1 / (a_1 + a_2), 0)t$. We can see that there exists arbitrage opportunity in the market. So, we assume that $c \leq \lambda \frac{a_1 + a_2}{a_1 a_2} \left(M_Y\left(\frac{a_1 a_2}{a_1 + a_2}\right) - 1\right)$. On the other hand, the positive safety loading condition requires that $c > \lambda \mu_1$. Therefore, in the rest of this paper, we assume that the following condition holds:
\[
\lambda \mu_1 < c \leq \lambda \frac{a_1 + a_2}{a_1 a_2} \left(M_Y\left(\frac{a_1 a_2}{a_1 + a_2}\right) - 1\right).
\]

(ii) For any $b, u \in [0, 1]$, we have
\[
|\mu(b, u)| \leq c + \frac{\lambda}{a_1} (M_Y(a_1) - 1) + \frac{\lambda}{a_2} (M_Y(a_2) - 1) + \lambda \mu_1 \triangleq M.
\]

Then similar to Proposition 3.1 of Cadenillas et al. [3], it is not difficult to derive that
\[
V(x) \leq k(x + |M|/\lambda).
\]

We now present the verification theorem.

**Theorem 3.2 (Verification Theorem).** Let $v(x) \in C^1((0, \infty))$ be a solution to (3.1) at all the points with the possible exception of some point where the second derivative may not exist. Suppose there exists $U > 0$ such that $v(x)$ is twice continuously differentiable on $(0, U)$ and $v(x)$ is linear on $[U, \infty)$. Then $V(x) \leq v(x)$, $x \geq 0$. Furthermore, if the QVI strategy $\alpha^v$ associated with $v(x)$ is admissible, then $v(x)$ coincides with the value function $V(x)$ and $\alpha^v$ is the optimal strategy, i.e., $V(x) = v(x) = V_{\alpha^v}(x)$, $x \geq 0$. 

6
Proof. Similar to the proof of Theorem 3.4 in Cadenillas et al. [3], it is not difficult to see that equations (3.17) and (3.18) of Cadenillas et al. [3] still hold for our model. So, one can apply Ito’s formula (even if the function \(v''\) might have a discontinuity of the first order at the point \(U\)) to get equations similar to those shown on page 187 of Cadenillas et al. [3], by replacing \(L^u\), \(\mu u_s\) and \(\sigma u_s\) by \(L^{b_u}v, \mu(b_s,u_s)\) and \(\sqrt{\lambda}\mu_2 b_s u_s\), respectively. Then, the remaining steps are the same as those in Cadenillas et al. [3].

4. Solution to the optimization problem

In order to derive explicit solution to the optimization problem, we consider the following two cases:

1. \(c < \lambda \frac{a_1 + a_2}{a_1 a_2} (M_Y\left(\frac{a_1 a_2}{a_1 + a_2}\right) - 1)\);
2. \(c = \lambda \frac{a_1 + a_2}{a_1 a_2} (M_Y\left(\frac{a_1 a_2}{a_1 + a_2}\right) - 1)\).

4.1. Case 1
4.1.1. Construction of solution

In this subsection, we try to construct a solution to (3.1) which satisfies the conditions in Theorem 3.2.

We first assume that there exists a strictly increasing solution \(W(x)\) to (3.1) which is continuously differentiable on \((0,\infty)\) and twice continuously differentiable on \((0,x_1)\), where \(x_1 = \inf\{x \geq 0 : M_Y(x) = V(x)\}\) (all of these will be proved later). Then, (3.1) with \(V\) replaced by \(W\) for \(0 \leq x < x_1\) can be rewritten as

\[
\max_{0 \leq b \leq 1, 0 \leq u \leq 1} \left\{ \frac{1}{2} \lambda \mu_2 u^2 W''(x) + \mu(b_t, u_t)W'(x) - \delta W(x) \right\} = 0. \tag{4.1}
\]

Let \(b(x)\) and \(u(x)\) be the maximizer of the left-hand side of (4.1) over all \(b, u \in (-\infty, \infty)\). Differentiating (4.1) with respect to \(u\) and \(b\) respectively, we get

\[
\frac{W''(x)}{W'(x)} = \frac{M_Y'(a_1(1-b(x))b(x)) - \mu_1}{\mu_2 b(x) u(x)}, \tag{4.2}
\]

\[
\frac{W''(x)}{W'(x)} = \frac{M_Y'(a_1(1-b(x)) - (1-u(x))M_Y'(a_2(1-u(x))b(x)) - u(x)\mu_1}{\mu_2 b(x)[u(x)]^2}. \tag{4.3}
\]

Combining (4.2) and (4.3), we have \(M_Y'(a_1(1-b(x))) = M_Y'(a_2(1-u(x))b(x))\). Then,

\[
a_1(1-b(x)) = a_2(1-u(x))b(x), \quad \text{i.e.,} \quad b(u(x)) = \frac{(a_1 + a_2)b(x) - a_1}{a_2}. \tag{4.4}
\]
Substituting (4.2) and (4.4) into (4.1), we have

\[ g(b(x))W'(x) - \delta W(x) = 0. \] (4.5)

where

\[ g(b) = -\frac{\lambda[(a_1 + a_2)b - a_1][M_Y'(a_1(1 - b)) - \mu_1]}{2a_2} + c - \frac{\lambda \mu_1[(a_1 + a_2)b - a_1]}{a_2} \]

\[-\left(\frac{1}{a_1} + \frac{1}{a_2}\right)\lambda[M_Y(a_1(1 - b)) - 1].\]

Differentiating (4.5) with respect to \( x \), we obtain

\[ \left[ \frac{dg(b(x))}{dx} - \delta \right] W'(x) + g(b)W''(x) = 0. \] (4.6)

Using (4.2) and (4.4) once again, we have

\[ W''(x) \left\{ \frac{dg(b(x))}{dx} - \delta - g(b(x)) \frac{a_2[M_Y'(a_1(1 - b(x))) - \mu_1]}{\mu_2[(a_1 + a_2)b(x) - a_1]} \right\} = 0. \] (4.7)

Since \( W'(x) > 0 \), and

\[ \frac{dg(b(x))}{dx} = \frac{\lambda}{2a_2} h(b(x))b'(x), \]

where

\[ h(b(x)) = (a_1 + a_2)[M_Y'(a_1(1 - b(x))) - \mu_1] + a_1[(a_1 + a_2)b(x) - a_1]M_Y''(a_1(1 - b(x))), \]

it follows from (4.7) that

\[ b'(x) = \frac{2a_2[\delta \mu_2[(a_1 + a_2)b(x) - a_1] + a_2g(b(x))[M_Y'(a_1(1 - b(x))) - \mu_1]]}{\lambda \mu_2[(a_1 + a_2)b(x) - a_1]h(b(x))}. \] (4.8)

In view of \( W(0) = 0 \) and (4.5), we know that \( b(0) \triangleq b_0 \) is a solution to \( g(b) = 0 \).

**Lemma 4.1.** The function \( g(b) \) is strictly increasing on \( [a_1/(a_1 + a_2), 1] \), and there exists a unique solution \( b_0 \) of \( g(b) = 0 \) on \( (a_1/(a_1 + a_2), 1] \).

**Proof.** For any \( b \in [a_1/(a_1 + a_2), 1] \), we have

\[ \frac{dg(b)}{db} = \frac{\lambda}{2a_2} \left\{ (a_1 + a_2)[M_Y'(a_1(1 - b)) - \mu_1] + a_1[(a_1 + a_2)b - a_1]M_Y''(a_1(1 - b)) \right\} > 0, \]

which implies that \( g(b) \) is increasing on \( [a_1/(a_1 + a_2), 1] \). Due to Remark 3.1, the result follows from

\[ \frac{a_1}{a_1 + a_2} = \mu \frac{a_1}{a_1 + a_2}, 0 < 0, \quad \text{and} \quad g(1) = c - \lambda \mu_1 > 0. \]
Let
\[ G(b) = \int_{b_0}^{b} \frac{\lambda \mu_2[(a_1 + a_2)y - a_1]h(y)}{2a_2\{\delta \mu_2[(a_1 + a_2)y - a_1] + a_2g(y)[M_y(a_1(1-y)) - \mu]\}} dy. \]  
(4.9)

Since \( g(y) > 0 \) for all \( b_0 < y \leq 1 \), the integrand in the right-hand side of (4.9) is positive on \( [b_0, 1] \). It is easy to see that \( G(b) \) is increasing on \( [b_0, 1] \), which implies that the inverse of \( G(b) \) exists on \( [b_0, 1] \). Furthermore, it is obvious that \([G(b(x))]' = 1 \), so \( b(x) = G^{-1}(x + k) \) for some constant \( k \). Since \( G(b_0) = 0 \), we have \( k = G(b_0) = 0 \) which results in
\[ b(x) = G^{-1}(x), \quad 0 \leq x \leq G(1). \]

By (4.4), we have
\[ u(x) = \frac{(a_1 + a_2)b(x) - a_1}{a_2b(x)}. \]

Let \( b^*(x) \) and \( u^*(x) \) be the maximizer of the left-hand side of (4.1) over all \( b, u \in [0, 1] \). Since \( b(G(1)) = u(G(1)) = 1 \), we guess that
\[ b^*(x) = \begin{cases} \frac{G^{-1}(x)}{1}, & 0 \leq x \leq G(1), \\ 1, & x > G(1) \end{cases} \quad \text{and} \quad u^*(x) = \begin{cases} \frac{(a_1 + a_2)G^{-1}(x) - a_1}{a_2G^{-1}(x)} - \frac{2}{a_2G^{-1}(x)}, & 0 \leq x \leq G(1), \\ 1, & x > G(1). \end{cases} \]

(4.10)

For \( 0 \leq x \leq G(1) \), (4.2) and (4.10) imply that
\[ (\ln W'(x))' = \frac{a_2[\mu_1 - M_y(a_1(1 - G^{-1}(x)))]}{\mu_2[(a_1 + a_2)G^{-1}(x) - a_1]}, \]
which leads to
\[ W(x) = q_1 \int_0^x \exp \left( \int_{G(1)}^z \frac{a_2[\mu_1 - M_y(a_1(1 - G^{-1}(y)))]}{\mu_2[(a_1 + a_2)G^{-1}(y) - a_1]} dy \right) dz, \]
(4.11)

where the constant \( q_1 > 0 \) will be determined later.

For \( G(1) < x \leq x_1 \), (4.1) becomes
\[ \frac{1}{2} \lambda \mu_2 W''(x) + (c - \lambda \mu_1)W'(x) - \delta W(x) = 0, \]
which has the following general solution
\[ W(x) = q_2 e^{r_+(x-G(1))} + q_3 e^{r_-(x-G(1))}, \]
(4.12)

where \( q_2 \) and \( q_3 \) are free constants, and
\[ r_+ = \frac{-(c - \lambda \mu_1) + \sqrt{(c - \lambda \mu_1)^2 + 2\lambda \delta \mu_2}}{\lambda \mu_2}, \quad r_- = \frac{-(c - \lambda \mu_1) - \sqrt{(c - \lambda \mu_1)^2 + 2\lambda \delta \mu_2}}{\lambda \mu_2}. \]
For $x > x_1$, by the definition of $x_1$, we guess that

$$W(x) = W(\tilde{x}) + k(x - \tilde{x}) - K,$$  \hspace{1cm} (4.13)

where $\tilde{x} < x_1$ is a constant that needs to be determined below.

We next try to determine the constants $q_1, q_2, q_3, \tilde{x}$ and $x_1$. By the continuity of $W'$ and $W''$ at $G(1)$, we obtain

$$q_2 r_+ + q_3 r_- = q_1, \quad q_2 r_+^2 + q_3 r_-^2 = 0,$$

which results in $q_2 = q_1 b_1$ and $q_3 = q_1 b_2$, where

$$b_1 = \frac{r_-}{r_+ (r_- - r_+)} > 0, \quad b_2 = \frac{r_+}{r_- (r_+ - r_-)} < 0. \hspace{1cm} (4.14)$$

Inspired by Bai et al. [2] or Cadenillas et al. [3], we will determine the unknown parameters $q_1, \tilde{x}$ and $x_1$ in the way that

$$W'(\tilde{x}) = W'(x_1) = k,$$

and

$$\int_\tilde{x}^{x_1} (k - W'(y)) dy = K.$$

Define an auxiliary function $U(x)$ as

$$U(x) = \begin{cases} 
\exp \left( \int_{G(1)}^x a_2 |a_1 - M'(a_1(1 - G^{-1}(y)))| dy \right), & 0 \leq x \leq G(1), \\
\frac{b_1 r_+ e^{r_+(x-\G(1))} + b_2 r_- e^{r_-(x-\G(1))}}{r_+ - r_-}, & x > G(1),
\end{cases}$$

which is equal to $W'(x)$ for $0 < x \leq x_1$. For $x \in [0, G(1))$, it is not difficult to see that

$$U'(x) < 0, \quad U''(x) > 0.$$

For $x > G(1)$, we have

$$U'(x) = b_1 r_+^2 e^{r_+(x-G(1))} + b_2 r_-^2 e^{r_-(x-G(1))} = b_1 r_+^2 [e^{r_+(x-G(1))} - e^{r_-(x-G(1))}] > 0,$$

$$U''(x) = b_1 r_+^3 e^{r_+(x-G(1))} + b_2 r_-^3 e^{r_-(x-G(1))} > 0.$$

So, the function $U(x)$ is convex on $(0, \infty)$. Since $U'(G(1)) = 0$, the function $U(x)$ attains its minimum at $x = G(1)$ with $U(G(1)) = 1$. From Figure 1, we have the following conclusions:
Figure 1: The graph of $qU(x)$. The area between the straight line $y = k$ and the graph of $qU(x)$ is equal to $K$.

(i) For any fixed $q \in (0, k]$, there always exists $\hat{x}_q \geq G(1)$ such that $qU(\hat{x}_q) = k$. Furthermore, if $q \downarrow 0$, then $\hat{x}_q \uparrow \infty$;

(ii) Let $\bar{q} = k/U(0) < k$. If $q \in [\bar{q}, k], qU(0) \geq k \geq q$, then there exists $\tilde{x}_q \in [0, G(1)]$ such that $qU(\tilde{x}_q) = k$. Besides, $\hat{x}_q$ is strictly decreasing with respect to $q$; $\tilde{x}_q$ is strictly increasing with respect to $q$; and $\hat{x}_q = \tilde{x}_q = G(1)$ for $q = k$.

Based on (i) and (ii), we consider

$$I_1(q) = \int_{\bar{x}_q}^{\hat{x}_q} (k - qU(y))dy, \quad I_2(q) = \int_0^{\bar{x}_q} (k - qU(y))dy.$$  

Then, it is not difficult to see that $I_1(q)$ is strictly decreasing with respect to $q$ on $[\bar{q}, k]$ and $0 = I_1(k) \leq I_1(\bar{q}) \leq I_1(q) \in (0, \infty)$, and that $I_2(q)$ is strictly decreasing on $[0, k]$, and

$$0 \geq \int_0^{G(1)} k(1 - U(y))dy = I_2(k) \leq I_2(q) \leq I_2(0) = \infty.$$  

Note that if $I_1(\bar{q}) > K$, then there exists a unique $q^* \in (\bar{q}, k)$ such that $I_1(q^*) = K$. Let $x_1 = \hat{x}_{q^*}$ and $\bar{x} = \tilde{x}_{q^*}$. Recalling that for any $x \leq x_1$, $W'(x) = qU(x)$, we have

$$W'(\tilde{x}_{q^*}) = W'(\hat{x}_{q^*}) = k, \quad W(\tilde{x}_{q^*}) = W(\hat{x}_{q^*}) + k(\hat{x}_{q^*} - \tilde{x}_{q^*}) - K;$$

and that if $I_1(\bar{q}) \leq K$, then there exists a unique $q^* \in (0, k)$ such that $I_2(q^*) = K$. Let $x_1 = \hat{x}_{q^*}$ and $\bar{x} = 0$. Then, we have

$$W'(\tilde{x}_{q^*}) = k, \quad W(\tilde{x}_{q^*}) = W(0) + k\hat{x}_{q^*} - K.$$

11
where the equality holds if and only if $\eta = W_\infty^{1}(y) = a_2 \frac{\mu_1 - a_2 (1 - G^{-1}(y))}{\mu_2 (1 - a_2 G^{-1}(y) - a_1)}$.

Theorem 4.1. The function $W(x)$ of (4.15) is continuously differentiable on $(0, \infty)$ and twice continuously differentiable on $(0, \hat{x}_{q^*}) \cup (\hat{x}_{q^*}, \infty)$. Furthermore, $W(x)$ is a solution to the QVI of (3.1).

Proof. Here, we only prove the case of $I_1(\tilde{q}) > K$. For the case of $I_1(\tilde{q}) \leq K$, it can be derived using similar arguments. From its construction, it is easy to see that $W(x)$ is continuously differentiable on $(0, \infty)$, and twice continuously differentiable on $(0, \hat{x}_{q^*}) \cup (\hat{x}_{q^*}, \infty)$. To complete the proof, we need to show that $W(x)$ is a solution to the QVI of (3.1).

Similar to the technique of Cadenillas et al. [3], we first prove that $M W(x) < W(x)$ for $0 < x < \hat{x}_{q^*}$, and that $M W(x) = W(x)$ for $x > \hat{x}_{q^*}$.

Since $U'(x) < 0$ for $0 < x < G(1)$, we see that $W'(x) = q^* U(x)$ is a strictly decreasing function on $[0, G(1)]$. Let $f(\eta) = W(x - \eta) + k \eta - K, 0 < \eta \leq x$. Note that $W'(\hat{x}_{q^*}) = k$. Hence, for any $x \leq \hat{x}_{q^*}$, we have $f'(\eta) = -W'(x - \eta) + k < 0$, which in turn yields

$$M W(x) = \sup_{0 < \eta \leq x} f(\eta) = f(0^+) = W(x) - K < W(x).$$

For $\hat{x}_{q^*} \leq x < \hat{x}_{q^*}$, $f'(x - \hat{x}_{q^*}) = -W'(\hat{x}_{q^*}) + k = 0$, then we obtain

$$M W(x) = f(x - \hat{x}_{q^*}) = W(\hat{x}_{q^*}) + k(x - \hat{x}_{q^*}) - K = W(\hat{x}_{q^*}) - k(\hat{x}_{q^*} - x) < W(x),$$

where the last inequality follows from $W'(x) < k$ for any $x \in (\hat{x}_{q^*}, \hat{x}_{q^*})$.

We now show that $M W(x) = W(x)$ for $x > \hat{x}_{q^*}$. If $\eta \in (0, x - \hat{x}_{q^*}]$, then

$$W(x - \eta) + k \eta - K = W(\hat{x}_{q^*}) + k(x - \eta - \hat{x}_{q^*}) - K + k \eta - K = W(x) - K < W(x).$$

If $\eta \in (x - \hat{x}_{q^*}, x]$, then

$$W(x - \eta) + k \eta - K = W(\hat{x}_{q^*} - [\eta - (x - \hat{x}_{q^*})] + k[\eta - (x - \hat{x}_{q^*}) - K + k(x - \hat{x}_{q^*})$$

$$\leq W(\hat{x}_{q^*}) + k(x - \hat{x}_{q^*}) = W(x),$$

where the equality holds if and only if $\eta = x - \hat{x}_{q^*}$. So, we have $M W(x) = W(x)$ for $x > \hat{x}_{q^*}$. 

We next prove that
\[
\begin{aligned}
\max_{0 \leq b \leq 1, 0 \leq u \leq 1} \mathcal{L}^{b,u} W(x) - \delta W(x) &= 0, \quad 0 < x < \hat{x}_{q^*}, \\
\max_{0 \leq b \leq 1, 0 \leq u \leq 1} \mathcal{L}^{b,u} W(x) - \delta W(x) &= 0, \quad x > \hat{x}_{q^*}.
\end{aligned}
\] (4.16)

For \(0 \leq x < G(1)\), we only need to prove that \(W(x)\) satisfies (4.5) with \(b(x) = G^{-1}(x)\). From its construction, we know that \(W(x)\) satisfies (4.6). This implies that \(W(x)\) should satisfy (4.5) with a constant (not necessarily equal to 0) on the right-hand side. Since \(g(b_0) = 0, W(0) = 0\) and
\[
W'(0) = q^* \exp \left( \int_0^{G(1)} \frac{a_2[M_Y'(a_1(1 - G^{-1}(y))) - \mu_1]}{\mu_2([a_1 + a_2]G^{-1}(y) - a_1)} dy \right)
\leq q^* \exp \left( \frac{a_2[M_Y'(a_1) - \mu_1]G(1)}{\mu_2([a_1 + a_2]b_0 - a_1)} \right) < \infty,
\]
the right-hand side of (4.5) tends to 0 when \(x \to 0\). It follows that \(W(x)\) satisfies (4.5) for all \(0 \leq x < G(1)\).

For \(G(1) \leq x \leq \hat{x}_{q^*}\),
\[
W'(x) = q^* U(x) \geq q^* > 0, \quad W''(x) = q^* U'(x) > 0.
\]

Then, for any fixed \(b \in [0, 1]\), we have
\[
\frac{\partial \mathcal{L}^{b,u} W(x)}{\partial u} = \lambda b^2 W''(x) + \lambda b[M_Y'(a_2(1 - u)b) - \mu_1]W'(x) > 0, \quad \forall u \in [0, 1].
\]

Therefore,
\[
\mathcal{L}^{b,u} W(x) \leq \mathcal{L}^{b,1} W(x) = \frac{1}{2} \lambda b^2 W''(x) + \left[ c - \frac{\lambda}{a_1} (M_Y(a_1(1 - b)) - 1) \right] - \lambda \mu_1 b W'(x).
\]

On the other hand,
\[
\frac{\partial \mathcal{L}^{b,1} W(x)}{\partial b} = \lambda b W''(x) + \lambda [M_Y'(a_1(1 - b)) - \mu_1]W'(x) > 0, \quad \forall b \in [0, 1].
\]

As a result, we obtain
\[
\max_{0 \leq b \leq 1, 0 \leq u \leq 1} \mathcal{L}^{b,u} W(x) = \mathcal{L}^{1,1} W(x) = \frac{1}{2} \lambda \mu_2 W''(x) + (c - \lambda \mu_1)W'(x).
\]

Finally, it follows from the construction of \(W(x)\) that
\[
\max_{0 \leq b \leq 1, 0 \leq u \leq 1} \mathcal{L}^{b,u} W(x) - \delta W(x) = \frac{1}{2} \lambda \mu_2 W''(x) + (c - \lambda \mu_1)W'(x) - \delta W(x) = 0.
\]
For $x > \hat{x}_q^*$, since $W(x) = W(\bar{x}_q^*) + k(x - \bar{x}_q^*) - K$, we have

$$\max_{0 \leq b \leq 1, 0 \leq u \leq \hat{x}_q^*} L^{b,u} W(x) - \delta W(x) = k \max_{0 \leq b \leq 1, 0 \leq u \leq 1} \mu(b, u) - \delta W(x)$$

$$= k\mu(1, 1) - \delta W(x) = k(c - \lambda \mu_1) - \delta W(x) < k(c - \lambda \mu_1) - \delta W(\hat{x}_q^*)$$

$$< \frac{1}{2} \lambda \mu_2 W'''(\hat{x}_q^*) + k(c - \lambda \mu_1) - \delta W(\hat{x}_q^*)$$

$$= L^{1,1} W(\hat{x}_q^*) - \delta W(\hat{x}_q^*) = 0.$$ 

Hence, (4.16) holds.

### 4.1.2. The value function and the optimal policy

Let

$$b_t^* = \begin{cases} G^{-1}(X_t^*), & 0 \leq X_t^* \leq G(1), \\ 1, & X_t^* > G(1), \end{cases} \quad u_t^* = \begin{cases} \frac{(a_1 + a_2)(G^{-1}(X_t^*) - a_1)}{a_2 G^{-1}(X_t^*)}, & 0 \leq X_t^* \leq G(1), \\ 1, & X_t^* > G(1), \end{cases}$$

and $\{\tau_n^*, \xi_n^*, n \geq 1\}$ are defined as follows:

(i) If $I_1(\bar{q}) > K$, then we define

$$\tau_1^* = \inf\{t > 0 : X_t^* = \hat{x}_q^*\}, \quad \xi_1^* = \hat{x}_q^* - \bar{x}_q^*,$$

when the initial surplus $0 < x < \hat{x}_q^*$,

$$\tau_1^* = 0, \quad \xi_1^* = x - \bar{x}_q^*,$$

when the initial surplus $x \geq \hat{x}_q^*$, and

$$\tau_n^* = \inf\{t > \tau_{n-1}^* : X_t^* = \hat{x}_q^*\}, \quad \xi_n^* = \hat{x}_q^* - \bar{x}_q^*,$$

for every $n \geq 2$, where $X_t^*$ is given by

$$X_t^* = x + \int_{0}^{t} \mu(b_t^*, u_t^*) dt + \int_{0}^{t} \lambda \mu_2 b_t^* u_t^* dW_t - (\hat{x}_q^* - \bar{x}_q^*) \sum_{n=1}^{\infty} I(\tau_n^* < t),$$

when the initial surplus $0 < x < \hat{x}_q^*$, and

$$X_t^* = x + \int_{0}^{t} \mu(b_t^*, u_t^*) dt + \int_{0}^{t} \lambda \mu_2 b_t^* u_t^* dW_t - (x - \bar{x}_q^*) I(\tau_1^* < t) - (\hat{x}_q^* - \bar{x}_q^*) \sum_{n=2}^{\infty} I(\tau_n^* < t),$$

when the initial surplus $x \geq \hat{x}_q^*$.
(ii) If \( I_1(q) \leq K \), then we define

\[
\tau^*_1 = \inf\{t > 0 : X^*_t = \hat{x}_q^*\}, \quad \xi^*_1 = \hat{x}_q^*,
\]

when the initial surplus \( 0 < x < \hat{x}_q^* \),

\[
\tau^*_1 = 0, \quad \xi^*_1 = x,
\]

when the initial surplus \( x \geq \hat{x}_q^* \), and

\[
\tau^*_n = \infty, \quad \xi^*_n = 0,
\]

for every \( n \geq 2 \), where \( X^*_t \) is given by

\[
X^*_t = x + \int_0^t \mu(b^*_t, u^*_t) dt + \int_0^t \sqrt{\lambda \mu_2 b^*_t u^*_t} dW_t, \quad t \leq \tau^*_1,
\]

when the initial surplus \( 0 < x < \hat{x}_q^* \).

**Theorem 4.2.** The value function \( V(x) \) is given by (4.15) and the strategy \( \alpha^* = (b^*_t; u^*_t; \tau^*_1; \tau^*_2, \cdots; \xi^*_1; \xi^*_2, \cdots) \) is the corresponding optimal policy.

**Proof.** It follows from Definition 3.1 and the arguments in the proof of Theorem 4.1 that \( \alpha^* = (b^*_t; u^*_t; \tau^*_1; \tau^*_2, \cdots; \xi^*_1; \xi^*_2, \cdots) \) defined above is the QVI strategy associated with \( W(x) \) which is given by (4.15). Besides, it is easy to see that \( \alpha^* \) is admissible. Hence, the optimal result is an immediate consequence of Theorem 3.2.

**4.2. Case 2**

In this subsection, we consider Case 2 with

\[
c = \lambda \frac{a_1 + a_2}{a_1 a_2} (M_Y(\frac{a_1 a_2}{a_1 + a_2}) - 1).
\]

To show that \( W(x) \) of (4.15) is the value function, and that \( \alpha^* \) in Theorem 4.2 is the optimal policy, one can apply arguments similar to those used in the previous subsection. However, from Lemma 4.1, we know that \( b_0 = a_1/(a_1 + a_2) \) in Case 2. Consequently, the integrand on the right-hand side of (4.9) and (4.11) might have a singularity. Therefore, we need to show that the integrals in the right-hand side of (4.9) and (4.11) make sense in this case.

**Proposition 4.3.**

\[
\lim_{x \to 0} b'(x) = \frac{2a_2 \delta \mu_2 + \lambda a_2 [M_Y'(\frac{a_1 a_2}{a_1 + a_2}) - \mu_1]^2}{\lambda \mu_2 (a_1 + a_2) [M_Y'(\frac{a_1 a_2}{a_1 + a_2}) - \mu_1]}. \tag{4.17}
\]
\textbf{Proof.} Note that \( b(x) \rightarrow a_1/(a_1 + a_2) \) and \( g(b(x)) \rightarrow g(a_1/(a_1 + a_2)) = 0 \) as \( x \rightarrow 0 \). Applying l’Hospital’s rule to the right-hand side of (4.8), we get

\[
\lim_{x \to 0} b'(x) = \lim_{b \to a_1/(a_1 + a_2)} \frac{2a_2 \{ \delta \mu_2[(a_1 + a_2)b - a_1] + a_2 g(b)[M_Y'(a_1(1 - b)) - \mu_1] \}}{\lambda \mu_2[(a_1 + a_2)b - a_1] h(b)}
\]

\[
= \frac{2a_2 \delta \mu_2(a_1 + a_2) + a_2 g'(a_1/(a_1 + a_2)) [M_Y'(a_1/(a_1 + a_2)) - \mu_1]}{\lambda \mu_2 (a_1 + a_2)^2 [M_Y'(a_1/(a_1 + a_2)) - \mu_1]}
\]

\[
= \frac{2a_2 \delta \mu_2 + \lambda a_2 [M_Y'(a_1/(a_1 + a_2)) - \mu_1]^2}{\lambda \mu_2 (a_1 + a_2) [M_Y'(a_1/(a_1 + a_2)) - \mu_1]}
\]

\textbf{Proposition 4.4.} Let \( G(b) \) be given in (4.9). Then, \( G(1) < \infty \).

\textbf{Proof.} Since

\[
G(1) = \int_{a_1/(a_1 + a_2)}^1 \frac{\lambda \mu_2[(a_1 + a_2)y - a_1] h(y)}{2a_2 \{ \delta \mu_2[(a_1 + a_2)y - a_1] + a_2 g(y)[M_Y'(a_1(1 - y)) - \mu_1] \}} \, dy,
\]

and the integrand in the above expression tends to

\[
\frac{\lambda \mu_2(a_1 + a_2) [M_Y'(a_1/(a_1 + a_2)) - \mu_1]}{2a_2 \delta \mu_2 + \lambda a_2 [M_Y'(a_1/(a_1 + a_2)) - \mu_1]^2}, \quad y \to \frac{a_1}{a_1 + a_2}.
\]

Hence, the results follows from Proposition 4.3.

\textbf{Proposition 4.5.} Let \( W(x) \) be given in (4.11). Then,

\[
W'(x) = q_1 \exp \left( \int_{G(1)}^x \frac{a_2 [\mu_1 - M_Y'(a_1(1 - b(y)))]}{\mu_2[(a_1 + a_2)b(y) - a_1]} \, dy \right) \sim x^{-n}, \quad x \to 0, \quad (4.18)
\]

where

\[
n = \frac{\lambda M_Y'(a_1/(a_1 + a_2)) - \mu_1^2}{2 \delta \mu_2 + \lambda M_Y'(a_1/(a_1 + a_2)) - \mu_1^2} < 1,
\]

and the notation \( f(x) \sim g(x) \) means that \( f(x)/g(x) \to c_1 \) for some constant \( c_1 > 0 \) as \( x \to 0 \).

\textbf{Proof.} It follows from (4.17) that

\[
b(x) - b(0) = \frac{2a_2 \delta \mu_2 + \lambda a_2 [M_Y'(a_1/(a_1 + a_2)) - \mu_1]^2}{\lambda \mu_2 (a_1 + a_2) [M_Y'(a_1/(a_1 + a_2)) - \mu_1]} x + o(x), \quad x \to 0. \quad (4.19)
\]

As a result, we obtain

\[
W'(x) \sim \exp \left( \int_{G(1)}^x \frac{a_2 [\mu_1 - M_Y'(a_1(1 - b(y)))]}{\mu_2[(a_1 + a_2)b(y) - a_1]} \, dy \right)
\]

\[
\sim \exp \left( - \int_{G(1)}^x \frac{a_2 [M_Y'(a_1/(a_1 + a_2)) - \mu_1]^2 \lambda \mu_2}{\mu_2(2a_2 \delta \mu_2 + \lambda a_2 [M_Y'(a_1/(a_1 + a_2)) - \mu_1]^2)} \, dy \right)
\]

\[
\sim x^{-2a_2 \delta \mu_2 + \lambda M_Y'(a_1/(a_1 + a_2)) - \mu_1^2}, \quad x \to 0.
\]
According to Proposition 4.5, we have the integrability at 0 of the integrand on the right-hand side of (4.11). Besides, from the proof of Theorem 4.1, we should verify that the right-hand side of (4.5) tends to 0 when \( x \to 0 \). Due to (4.18) and (4.19), we have:

\[
W'(x) \sim \left(b(x) - \frac{a_1}{a_1 + a_2}\right)^{-n}, \quad x \to 0.
\]

Therefore, it is sufficient to show that

\[
\lim_{b \to \frac{a_1}{a_1 + a_2}} g(b) \left( b - \frac{a_1}{a_1 + a_2} \right)^{-n} = 0.
\]

Applying l'Hospital’s rule, we get

\[
\lim_{b \to \frac{a_1}{a_1 + a_2}} \left[ c - \left( \frac{1}{a_1} + \frac{1}{a_2} \right) \lambda M_Y(a_1(1-b)) - 1 \right] \left( b - \frac{a_1}{a_1 + a_2} \right)^{-n} = 0,
\]

which implies that the right-hand side of (4.5) tends to 0 as \( x \to 0 \).

5. Some comments

The problem studied in Chen et al. [4] can be extended to the case of two reinsurers, which is also the case without transaction costs of this paper. Take the unbounded dividend rates for example. Following the arguments in Chen et al. [4], we know that the value function \( V(x) \) satisfies (4.1) for \( 0 \leq x < x_1 \) and \( V'(x) = 1 \) for \( x \geq x_1 \), where \( x_1 = \inf\{ x \geq 0 : V'(x) \leq 1 \} = G(1) \). Since \( V'(x_1) = 1 \), it is easy to see that \( q_1 = 1 \) in (4.11) and \( V(x_1) = \frac{c - \lambda \mu_1}{\delta} \) by (4.5). Therefore, the value function \( V(x) \) is given by

\[
V(x) = \begin{cases} 
\int_0^x \exp \left( \int_{G(1)}^z a_2 \frac{\mu_1 - M_Y'(a_1(1-G^{-1}(y)))}{\mu_2 [(a_1 + a_2)G^{-1}(y) - a_1]} \, dy \right) \, dz, & 0 \leq x \leq G(1), \\
\frac{c - \lambda \mu_1}{\delta} + x - G(1), & x > G(1),
\end{cases}
\]

and the optimal reinsurance strategy is given by (4.10).

6. Numerical example

The influence of \( k \) and \( K \) on the critical levels \( \hat{x}_q \) and \( \tilde{x}_q \) are clear from Figure 1. Since the effects of \( a_1 \) and \( a_2 \) (risk aversion parameters of the reinsurers) on the critical levels \( \hat{x}_q \) and \( \tilde{x}_q \) are rather complicated, we give a numerical example to illustrate the effects of \( a_1 \) and \( a_2 \) on the optimal reinsurance strategy in this section. In the example,
we assume that the claim sizes are exponentially distributed with parameter 1, and set $\lambda = 1$, $c = 3/2$, and $\delta = 0.05$. By fixing $a_1 = 1$ and taking $a_2 = 0.6, 0.8, 1, 1.5, 2$, the optimal proportions on $[0, G(1)]$ for the insurer and two reinsurers are exhibited in Figures 2-4, and the values of $G(1)$ are given in Table 1.

From Figures 2-4, we see that the effect of $a_2$ wears off as $a_2$ increases. Figures 2 and 4 show that, when $a_2$ changes, the impact on the optimal proportions of the insurer and the second reinsurer is significant for small initial surplus, and becomes weaker for large initial surplus. Finally, we observe from Figure 3 that for the first reinsurer, the impact of $a_2$ on $1 - b^*(x)$ increases to a certain level as the initial surplus increases, and remains at that level for large initial surplus (the lines in Figure 3 are almost parallel when the initial surplus is more than 1.5).
