Abstract: In optical dating of potassium-feldspar, the luminescence signals can be stimulated by both infrared (IR) light and blue light (BL). To develop reliable dating methods using different stimulation light sources for feldspars, it is important to understand the sources of the traps associated with the infrared stimulated luminescence (IRSL) and blue light stimulated luminescence (BLSL) and their relationship. In this study, we explored the luminescence characteristics of IRSL and BLSL at different stimulation temperatures (from 60 °C to 200 °C) and their relationship based on five sets of experiments, i.e. post-IR BLSL, post-BL IRSL experiments, pulse annealing test, dose response test and laboratory fading rate test. Our results suggest that the luminescence characteristics of IRSL and BLSL and their relationship are dependent on stimulation temperature. For IR stimulation at a relatively high temperature of 200 °C, at least two components of IRSL signals are involved in the process. One component of IRSL signals can be easily bleached by BL stimulation at 60 °C, while the other is relatively hard to be bleached by BL stimulation at 60 °C. The two components have different luminescence properties, such as thermal stability, dose response and laboratory fading rate.

11 **Abstract:**

12 In optical dating of potassium-feldspar, the luminescence signals can be stimulated  
13 by both infrared (IR) light and blue light (BL). To develop reliable dating methods  
14 using different stimulation light sources for feldspars, it is important to understand the  
15 sources of the traps associated with the infrared stimulated luminescence (IRSL) and  
16 blue light stimulated luminescence (BLSL) and their relationship. In this study, we  
17 explored the luminescence characteristics of IRSL and BLSL at different stimulation  
18 temperatures (from 60 °C to 200 °C) and their relationship based on five sets of  
19 experiments, i.e. post-IR BLSL, post-BL IRSL experiments, pulse annealing test, dose  
20 response test and laboratory fading rate test. Our results suggest that the luminescence  
21 characteristics of IRSL and BLSL and their relationship are dependent on stimulation  
22 temperature. For IR stimulation at a relatively high temperature of 200 °C, at least two  
23 components of IRSL signals are involved in the process. One component of IRSL  
24 signals can be easily bleached by BL stimulation at 60 °C, while the other is relatively  
25 hard to be bleached by BL stimulation at 60 °C. The two components have different  
26 luminescence properties, such as thermal stability, dose response and laboratory fading  
27 rate.

31 **1. Introduction**

32

33 Both quartz and potassium-rich feldspar (K-feldspar) have been widely used as  
34 natural dosimeters for optically stimulated luminescence (OSL) dating (Aitken, 1998).  
35 Compared with quartz OSL, the infrared stimulated luminescence (IRSL) signal from  
36 K-feldspar (Hütt et al., 1988) has advantages of much brighter luminescence signals  
37 and much higher dose saturation level, making feldspar as an attractive candidate for  
38 luminescence dating of the natural sedimentary samples. However, the usage of  
39 K-feldspar for dating has long been hindered by the anomalous fading of the trapped  
40 charges related to the IRSL signals (e.g. Spooner, 1994; Huntley and Lamonthé, 2001;  
41 Li and Li, 2008).

42 More recently, progress in understanding anomalous fading in feldspar has raised  
43 the prospect of isolating a non-fading component from the IRSL at relatively high  
44 temperatures (Thomsen et al., 2008; Li, 2010; Jain and Ankjærgaard, 2011; Li and Li,  
45 2013). Correspondingly, a two-step post IR IRSL (pIRIR) protocol (Buylaert et al.,  
46 2009; Thiel et al., 2011) and a multi-elevated-temperature post-IR IRSL (MET-pIRIR)  
47 protocol (Li and Li, 2011a) have been proposed to overcome anomalous fading for  
48 dating K-feldspar from sediments, which offer the promising potential for extending  
49 the luminescence dating limit (Thiel et al., 2011; Li and Li, 2012; Li et al., 2013,  
50 However, the high temperature pIRIR signals (e.g. >200 °C) ~~isare~~ found to be more  
51 difficult to bleach than the IRSL signals measured at lower temperatures (Li and Li,  
52 2011a; Buylaert et al., 2012; Murray et al., 2012), and it usually requires up to several  
53 hours or even days of exposure to sunlight or a solar simulator to bleach the pIRIR  
54 signals down to a stable level (here the term “bleach” means to reduce the  
55 luminescence intensity by optical stimulation). For some samples, a significant  
56 non-bleachable (or residual) component in the pIRIR signals was left even after a  
57 prolonged bleaching period using solar simulator or sunlight (Buylaert et al., 2011;  
58 Lowick et al., 2012; Chen et al., 2013; Li et al., 2014b). These studies suggest that the  
59 IRSL signals recorded at relatively high temperature have different luminescence  
60 behavior compared with the IRSL signals at room temperature.

61 There have been several studies conducted to explore the relationship between

62 luminescence with IR stimulation and luminescence with visible wavelength light  
63 stimulation. It was demonstrated that the majority of green light stimulated  
64 luminescence (GLSL) can be bleached by prolonged IR light and an upper limit of ~  
65 90% GLSL was depleted as a result of IR bleaching at room temperature (Duller and  
66 Bøtter-Jensen, 1993; Galloway, 1994). Jain and Singhvi (2001) concluded that the  
67 blue-green (BG) stimulated luminescence measured at 125 °C is associated with at  
68 least two trap populations. One trap population is responsive to both IR stimulation  
69 and BG stimulation. Another trap population is only responsive to BG stimulation.  
70 Gong et al. (2012) conducted a study on the relationship between the infrared  
71 stimulated luminescence (IRSL) and blue light stimulated luminescence (BLSL) at  
72 60 °C. They observed that most of the IRSL signals at 60 °C can be bleached by BL at  
73 60 °C, while the BLSL signals at 60 °C can only be partially bleached by IR at 60 °C.  
74 The sources for the IRSL at 60 °C are mainly associated with the fast and medium  
75 components of the BLSL at 60 °C.

76 In this study, in order to better understand the sources of the traps associated with  
77 the IRSL and BLSL, we further explore the relationship between IRSL and BLSL  
78 using K-feldspar from two aeolian sand samples. The luminescence properties, in  
79 terms of thermal stability, dose response and laboratory fading rate, are also examined  
80 for the different IRSL components at a relatively high temperature of 200 °C.

81

## 82 2. Samples and equipment

83

84 Two aeolian sand samples (HSDK-11 and SY) from the Hunshandake desert in  
85 northeast China were used in this study. Both samples have been investigated in  
86 previous studies (Li et al., 2002; Gong et al., 2013). The samples are from the same  
87 environmental settings of the same region and have similar luminescence behaviors,  
88 so the experimental results obtained from them should be comparable. The samples  
89 were treated with 10 % hydrochloric acid (HCl) and 10 % hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>)  
90 to remove carbonate and organic matter, respectively, in subdued red light in the

91 Luminescence Dating Laboratory, the University of Hong Kong. Grains of 150-180  
92  $\mu\text{m}$  in diameter were obtained by dry sieving. The K-feldspar grains were separated  
93 with heavy liquids ( $2.58 \text{ g}\cdot\text{cm}^{-3}$ ) and then etched for 40 min with diluted (10 %)   
94 hydrofluoric acid (HF) to clean the grains. HCl (10 %) was used again to dissolve any  
95 contaminating fluorides after etching before final rinsing and drying. K-feldspar  
96 grains were prepared by mounting the grains in a monolayer, on a 9.8 mm diameter  
97 aluminum disc with “Silkospay” silicone oil.

98 The luminescence measurements of the sample HSDK-11 were carried out with an  
99 automated Risø TL-DA-15 reader equipped with an IR LED array (880 nm, FWHM  
100 40 nm) and a blue LED array (470 nm, FWHM 20 nm) in the Luminescence Dating  
101 Laboratory, the University of Hong Kong. The IR and BL stimulations deliver  $\sim 135$   
102  $\text{mW}\cdot\text{cm}^{-2}$  and  $\sim 50 \text{ mW}\cdot\text{cm}^{-2}$  at the sample position, respectively (Bøtter-Jensen et al.,  
103 2003). To keep our results comparable with those from Gong et al. (2012), 90% of the  
104 full power was used for stimulation in this study. Irradiations were carried out within  
105 the reader using a  $^{90}\text{Sr}/^{90}\text{Y}$  beta source which delivered a dose rate of  $0.0761 \text{ Gy}\cdot\text{s}^{-1}$  to  
106 K-feldspar on aluminum discs. The IRSL and the BLSL signals were both detected  
107 after passing through 7.5-mm-thick U-340 filters, which mainly pass light from 290  
108 nm to 370 nm with peak transmission at  $\sim 340 \text{ nm}$  (Li et al., 2007b). The experimental  
109 work on the other sample SY was performed in the Luminescence Dating Laboratory,  
110 Institute of Geology and Geophysics, Chinese Academy of Sciences. The  
111 luminescence measurements of the sample SY were carried out with an automated  
112 Risø TL/OSL reader (TL/OSL-DA-15) using the similar equipment setting. The  
113  $^{90}\text{Sr}/^{90}\text{Y}$  beta source in the equipment delivered a dose rate of  $0.0837 \text{ Gy}\cdot\text{s}^{-1}$  to  
114 K-feldspar on aluminum discs.

115

116

### 117 3. Experimental details and results

118

119 3.1 The relationship between the IRSL and the BLSL at different stimulation  
120 temperatures

121 Two sets of experiments, namely post-IR BLSL (pIR-BLSL) and post-blue light  
122 IRSL (pBL-IRSL), are conducted to investigate the relationship between the IRSL and  
123 the BLSL at different stimulation temperatures. For simplification, we describe the  
124 stimulation temperatures used in the prior IR and post-IR BLSL as pIR( $T_1$ )-BLSL( $T_2$ ),  
125 where  $T_1$  is the stimulation temperature used in the prior IR measurement and  $T_2$  is  
126 the temperature used in post-IR BLSL measurement.

127

### 128 3.1.1 pIR-BLSL experiments

129

130 The pIR-BLSL experiments were carried out using the procedure listed in Table 1.  
131 Four aliquots of K-feldspar grains HSDK-11 were firstly heated to 500 °C and then  
132 given a dose of 30.4 Gy. These aliquots were subsequently preheat at 280 °C for 10 s  
133 and then bleached using IR stimulation at a temperature of  $T_1$  for different periods  
134 ranging from 0 to 5000 s. The pIR-BLSL signal ( $L_x$ ) was then measured at a  
135 temperature of  $T_2$ . After that, a test dose of 15.2 Gy was applied and the induced  
136 BLSL signal ( $T_x$ ) was measured following the same preheat to monitor sensitivity  
137 change for  $L_x$ . The signals for both  $L_x$  and  $T_x$  were calculated from the integrated  
138 photon counts in the first 1 s of stimulation, with subtraction of the instrumental  
139 background signal. The experiments are conducted at a set of different temperature  
140 combinations, i.e. pIR(60)-BLSL(60), pIR(100)-BLSL(60), pIR(150)-BLSL(60),  
141 pIR(200)-BLSL(60) and pIR(200)-BLSL(200), respectively.

142 The IR bleaching effects on the pIR-BLSL signal for different periods of time are  
143 shown in Fig. 1. It is observed that the IR bleaching at higher temperatures can  
144 deplete the BLSL at 60 °C at a faster rate than IR stimulation at lower temperatures.  
145 The BLSL at 60 °C was bleached to about 5 % of the initial intensity after IR  
146 bleaching at 200 °C for 5000 s. In comparison, the BLSL at 60 °C was bleached to  
147 about 15 % of the initial intensity after IR bleaching at 60 °C for 5000 s. If we  
148 increase the stimulation temperature in BLSL from 60 to 200 °C, i.e. pIR(200)-BLSL  
149 (200), the IR stimulation at 200 °C can bleach the most of the traps associated with  
150 the BLSL at 200 °C and only 6 % of the initial intensity of the BLSL at 200 °C was

151 remaining after IR bleaching at 200 °C for 5000 s (Fig. 1). The results suggest that  
152 both the BLSL measured at 60 °C and the BLSL at 200 °C can only be partially  
153 bleached by prolonged (up to 5000 s) IR stimulation even at a relatively high  
154 temperature (i.e. 200 °C).

155 In our previous study (Gong et al., 2012), it was found that the BLSL signals  
156 measured at 60 °C for the K-feldspar from sample HSDK-11 can be described using  
157 three first-order exponential components, which are termed as fast (F), medium (M)  
158 and slow (S) components. Gong et al. (2012) demonstrated that the sources for the  
159 IRSL at 60 °C are mainly associated with the fast and medium components of the  
160 BLSL at 60 °C. To further demonstrate the relationship between IRSL signal at  
161 relatively high temperatures and BLSL at 60 °C, the residual BLSL at 60 °C after IR  
162 bleaching for different time from 0 s to 5000 s were then fitted using three OSL  
163 components. It is found that the pIR-BLSL signals can be well described by the three  
164 exponential functions (all  $R^2 > 0.96$ ). The relative ratios of the decay rates of the  
165 components of BLSL at 60 °C, i.e.  $b_f/b_m$  and  $b_m/b_s$ , are calculated at  $4.87 \pm 0.14$  and  
166  $10.69 \pm 0.41$ , respectively (here the parameters of  $b_f$ ,  $b_m$  and  $b_s$  refer to the decay rate  
167 of the fast, medium and slow components of BLSL at 60 °C, respectively). It is noted  
168 that the assumption of that the BLSL process is first-order may not be true. However,  
169 this will not influence our conclusion because it is the relationship between the  
170 different parts of BLSL (represented by the fast, medium and slow components) and  
171 IRSL that is crucial for our study, rather than whether these components are first-order  
172 or not. We, however, acknowledge that there may be some uncertainty associated with  
173 the fitting and some results demonstrated by Fig. 2 and Fig. 6 might be partially  
174 influenced if these components are not first-order.

175 Fig. 2a illustrates four representative pIR-BLSL signals, which are fitted into three  
176 components. The results of IR bleaching for the fast, medium and slow component of  
177 BLSL at 60 °C are shown in Fig. 2b. It is observed that the IR stimulation at 200 °C  
178 for 5000 s can deplete 99 % of the fast component, ~99 % of the medium component  
179 but only ~38 % of the slow component for the BLSL at 60 °C, while IR stimulation at  
180 60 °C for 5000 s can only deplete ~97 % of fast component, ~91 % of medium

181 component and ~12 % of slow component, respectively, for the BLSL at 60 °C. These  
182 results indicate that IRSL obtained at 200 °C involves more traps associated with  
183 hard-to-bleach components (i.e. the medium and slow components) of BLSL at 60 °C  
184 than does the IR stimulation at 60 °C. The results are consistent with previous studies  
185 that the IRSL signals at high temperatures (e.g. >200 °C) are relatively harder to  
186 bleach than the IRSL at 60 °C (Buylaert et al., 2011; Li and Li, 2011a; Chen et al.,  
187 2013).

188 The relationship between the IRSL and BLSL at different temperatures is further  
189 studied by investigating the relationship between the emitted light counts from the  
190 IRSL and the corresponding lost counts obtained from the pIR( $T_1$ )-BLSL( $T_2$ )  
191 experiments ( $T_1$ = 60, 100, 150, 200 °C;  $T_2$ = 60, 200 °C). This is similar to the method  
192 applied to study the relation between IRSL and thermoluminescence (TL) by Duller  
193 (1995). In Fig. 3, we plot the emitted counts from the IRSL, against the corresponding  
194 lost counts of the pIR-BLSL as a result of IR bleaching. It is observed that, if the  
195 stimulation temperature for IR and BL was identical in both cases (i.e.  
196 pIR(60)-BLSL(60) and pIR(200)-BLSL(200)), the emitted counts of the IRSL have a  
197 nearly 1:1 relationship with the corresponding lost counts in the pIR-BLSL. However,  
198 in the case of  $T_1 > T_2$ , the emitted counts of the IRSL are larger than the corresponding  
199 lost counts in pIR-BLSL, indicating that the relationship between BLSL and IRSL is  
200 dependent on the stimulation temperature. It is to be noted that such a relationship  
201 between IRSL and BLSL is not influenced by the interference of isothermal TL,  
202 because the preheat at 280 °C for 10 s is sufficient to remove any isothermal TL at  
203 200 °C. One straightforward explanation for the temperature dependency of the  
204 relationship is that at least two components are involved in the IRSL at the relatively  
205 high temperature (such as the IRSL at 200 °C). One component is responsive to the  
206 BL at 60 °C. The other is hard to reach by BL at 60 °C, but can be accessed at higher  
207 temperatures. The results further support fact that the IRSL signals at relatively high  
208 temperatures are relatively harder to bleach than the IRSL at 60 °C (e.g. Chen et al.,  
209 2013).

210

### 211 3.1.2 pBL-IRSL experiments

212

213 The effects of BL bleaching at 60 °C and 200 °C on the IRSL signals at different  
214 temperatures (60, 100, 150 and 200 °C) are investigated using pBL-IRSL experiments  
215 (see the procedures listed in Table 1). The experiments conducted are  
216 pBL(60)-IRSL(60), pBL(60)-IRSL(100), pBL(60)-IRSL(150), pBL(60)-IRSL(200)  
217 and pBL(200)-IRSL(200), respectively. Four aliquots of K-feldspar grains of  
218 HSDK-11 were firstly heated to 500 °C to remove any residual signals and then given  
219 the same irradiation dose of 30.4 Gy. These aliquots were then held at 280 °C for 10 s.  
220 They were subsequently bleached with BL at 60, 200 °C for different periods from 0  
221 to 320 s before IRSL measurements. After that, the IRSL sensitivity was monitored  
222 and measured following a test dose of 15.2 Gy and preheat at 280 °C for 10 s.

223 The remnant IRSL at different temperatures (50, 100, 150 200 °C) as a result of  
224 BL bleaching at 60, 200 °C for different periods of times are shown in Fig. 4. It is  
225 demonstrated that the IRSL at 60 °C can be bleached to a negligible level (~0.2 %) by  
226 BL stimulation at 60 °C for 320 s, while 3.5 % of the initial IRSL at 200 °C still  
227 remains after BL bleaching at 60 °C for 320 s. These results indicate that, compared  
228 with the IRSL at 60 °C, the IRSL at 200 °C involves more traps that are harder to  
229 bleach by BL at 60 °C. However, the IRSL at 200 °C can be bleached to a negligible  
230 level (~0.2 %) by BL stimulation at 200 °C for 320 s. In addition, the decay rates in  
231 the pBL(200)-IRSL (200) and the pBL(60)-IRSL(60) are very similar and they are  
232 calculated at  $0.23 \pm 0.02 \text{ s}^{-1}$  and  $0.21 \pm 0.01 \text{ s}^{-1}$ , respectively. These results further  
233 suggest that the relationship between the IRSL and the BLSL is dependent on  
234 stimulation temperature.

235 Further investigation is made on the relationship between the emitted counts from  
236 the BLSL and the corresponding lost counts from pBL( $T_1$ )-IRSL( $T_2$ ) ( $T_1= 60, 200 \text{ °C}$ ;  
237  $T_2= 60, 100, 150, 200 \text{ °C}$ ) (Fig. 5). It is observed that the emitted counts from the  
238 BLSL measured both at 60 °C and at 200 °C are significantly larger than the  
239 corresponding lost counts from pBL( $T_1$ )-IRSL( $T_2$ ). These results indicate that BL can

240 access much more traps than IR stimulation. Only part of traps associated with the  
241 BLSL at 60 °C and at 200 °C is accessible by IR stimulation, which is similar to the  
242 results of IRSL observed at 60 °C (Gong et al, 2012). It is also demonstrated that  
243 relationship between emitted BLSL counts and lost counts of pBL-IRSL changes as  
244 the stimulation temperature changes.

245 To further demonstrate the relationship between different OSL components of the  
246 BLSL signal at 60 °C and the IRSL signals at relatively high temperatures, the emitted  
247 light counts from different OSL components of the BLSL signal at 60 °C are  
248 compared with the corresponding lost counts from the pBL(60)-IRSL(200) and  
249 pBL(60)-IRSL(60) as a result of BL bleaching at 60 °C for different periods. We plot  
250 the emitted counts from the various OSL components of the BLSL at 60 °C, against  
251 the lost counts of IRSL at 60 °C and IRSL at 200 °C as a result of BL bleaching in Fig.  
252 6. It is observed that the lost counts in pBL(60)-IRSL(200) are larger than the sum of  
253 the emitted light counts of the fast and medium components of BLSL at 60 °C, while  
254 the lost counts in pBL(60)-IRSL(60) have a nearly 1:1 relationship with the sum of  
255 the emitted light counts of the fast and medium components of BLSL at 60 °C. These  
256 results indicate that the IRSL signals at 200 °C are involved with not only the fast and  
257 medium components of BLSL at 60 °C, but also some other OSL components (e.g.  
258 slower components of BLSL at 60 °C). In contrast, there is a close relationship  
259 between IRSL at 60 °C and the fast and medium components of BLSL at 60 °C (Gong  
260 et al., 2012). The results are consistent with the observations in previous section 3.1.1.

261 In summary, the results from the pIR-BLSL and pBL-IRSL bleaching experiments  
262 suggest that the relationship between IRSL and BLSL is dependent on stimulation  
263 temperature. At least two components of traps are involved in the IRSL measured at  
264 elevated temperatures (e.g., 200 °C). One component can be easily bleached by BL at  
265 60 °C, and the other of the IRSL is relatively harder to access by BL at 60 °C. The  
266 results show that the IRSL signals at relatively high temperatures are harder to be  
267 bleached than the IRSL at room temperature.

268

269 3.2 Luminescence properties of IRSL at relatively high temperature

270

271 The luminescence characteristics of the IRSL at 200 °C, the pIR(60)-IRSL(200)  
272 and the pBL(60)-IRSL(200), including thermal stability, dose response and laboratory  
273 fading rate, were further investigated. In both the pIR(60)-IRSL(200) and the  
274 pBL(60)-IRSL(200) experiments, the IR and BL bleaching time was both fixed at 200  
275 s.

276

### 277 3.2.1 Thermal stability study

278

279 The thermal stability studies are carried out using the pulse annealing test (Table 2)  
280 (Li et al., 1997; Li and Tso, 1997). The tests were conducted for the IRSL at 60 °C,  
281 the IRSL at 200 °C, the pIR(60)-IRSL(200) and the pBL(60)-IRSL(200), respectively.  
282 An aliquot of K-feldspar of SY was firstly heated to 500 °C and then given an  
283 irradiation dose of 30.4 Gy. After that, it was preheated at 280 °C for 10 s and then  
284 heated to a temperature at T °C before the remaining IRSL was measured at 60 °C for  
285 160 s. The sensitivity change was monitored by measuring the IRSL signal at 60 °C  
286 from a test dose of 30.4 Gy. The same preheat condition (280 °C for 10 s) was applied  
287 for the test dose IRSL measurement. This cycle was repeated by increasing the  
288 annealing temperature (T) from 160 °C to 500 °C in steps of 20 °C. The similar pulse  
289 annealing test procedures were also conducted for the IRSL at 200 °C, the  
290 pIR(60)-IRSL(200) and the pBL(60)-IRSL(200) (Table 2). The heating rate for all  
291 these pulse annealing experiments was 3 °C·s<sup>-1</sup>.

292 The typical decay curve of the pBL(60)-IRSL(200) signal is shown in Fig. 7. The  
293 results of the pulse annealing test of the IRSL at 60 °C, the IRSL at 200 °C, the  
294 pIR(60)-IRSL(200) and the pBL(60)-IRSL(200) are shown in Fig. 8. It is observed  
295 that the thermal stability of the IRSL at 200 °C is relatively more stable than that of  
296 the IRSL at 60 °C. Li and Li (2011b; 2013) also observed the different thermal  
297 stabilities among the IRSL at different stimulation temperatures. In addition, it is  
298 found that both pIR(60)-IRSL(200) and pBL(60)-IRSL(200) is more thermally stable  
299 than IRSL at 200 °C. The results suggest that at least two components are involved in

300 the IRSL at 200 °C and the components have significantly different thermal stability.  
301 Both IR at 60 °C and BL at 60 °C can remove the thermally relatively unstable  
302 component of IRSL 200 °C. It is interesting to be noted that the pBL(60)-IRSL(200)  
303 is significantly more thermally stable than pIR(60)-IRSL(200), indicating that the BL  
304 at 60 °C is more efficient than IR at 60 °C to reduce thermally unstable component in  
305 the IRSL at 200 °C.

306

### 307 3.2.2 Dose response curves

308

309 Different shapes of dose response curve (DRC) may provide an indication of  
310 different origins of different luminescence signals (Gong et al., 2012). Here we  
311 compare the DRC of the IRSL at 200 °C from K-feldspar with that of the  
312 pBL(60)-IRSL(200). Regenerative doses ranging from 0 to 1950 Gy were employed  
313 in a single aliquot regeneration (SAR) protocol for the IRSL at 200 °C. A test dose of  
314 52 Gy was applied and the test dose signal ( $T_x$ ) was measured to monitor and correct  
315 for sensitivity change. A recycle dose at 26 Gy was used and the recycling ratios all  
316 fall within the range of  $1.0 \pm 0.05$  for the sample. The preheat temperature (held at  
317 280 °C for 10 s) was the same for regeneration and test dose measurements. A  
318 cut-heat to 500 °C was used between each of the SAR cycles to clean the residual  
319 signals from the previous cycle. The IRSL signals  $L_x$  and  $T_x$  were calculated from the  
320 integrated photon counts in the first 1 s of stimulation, with subtraction of a  
321 background signal derived from the last 10 s of the 160 s stimulation. For construction  
322 the DRC of the pBL(60)-IRSL(200), a similar SAR procedure was applied, except  
323 that a BL bleaching at 60 °C for 200 s was added before each IRSL measurement for  
324 both the regenerative and test dose measurements. The dose response curves for the  
325 two signals are shown in Fig. 9. It is found that the pBL(60)-IRSL(200) signal have a  
326 different dose saturation level with the IRSL at 200 °C.

327 If the two dose response curves are fitted with double saturation exponential  
328 function (equation 1),

329 
$$I = I_0 + I_a(1 - \exp(-D/D_{0,a})) + I_b(1 - \exp(-D/D_{0,b})) \quad (1)$$

330 The dose saturation level of two  $D_0$  ( $D_{0,a}$  and  $D_{0,b}$ ) parameters are  $42.9 \pm 5.8$  Gy  
 331 and  $289.7 \pm 22.4$  Gy for the pBL(60)-IRSL(200) signal, while the values of two  $D_0$   
 332 ( $D_{0,a}$  and  $D_{0,b}$ ) parameters of the IRSL at 200 °C are significantly higher at  $214.6 \pm 9.9$   
 333 Gy and  $806.1 \pm 69.6$  Gy, respectively. The results indicate that at least two components  
 334 are involved in the IRSL at elevated temperature. One group is easy to bleach by BL  
 335 at 60 °C and they have a higher dose saturation level, while the other group is hard to  
 336 bleach by BL at 60 °C and they have a lower dose saturation level.

337

### 338 3.2.3 Laboratory fading test

339

340 Anomalous fading was observed for both IRSL and BLSL signals in previous  
 341 studies (e.g. Thomsen et al., 2008). Here we studied the laboratory fading rates for the  
 342 IRSL at 200 °C, the pIR(60)-IRSL(200) and the pBL(60)-IRSL(200) signals. In  
 343 measurement of the IRSL at 200 °C, six aliquots of SY were heated to 500 °C to  
 344 remove any residual signals (similar to a hot-bleach between SAR cycles). Then these  
 345 aliquots were given 50.8 Gy and immediately preheated at 280 °C for 10 s. The  
 346 sensitivity corrected signals were then measured after delays of different periods. For  
 347 the test dose, 12.7 Gy was given and the same preheat condition was applied. The  
 348 IRSL signals  $L_{(x)}$  and  $T_{(x)}$  were calculated from the integrated photon counts in the  
 349 first 1 s of stimulation, with subtraction of a background signal derived from the last  
 350 10 s of the 160 s stimulation. The first measurement of the IRSL at 200 °C signal took  
 351 place at a time  $t_c = 562$  s after the mid-point of the irradiation time. A similar  
 352 measurement procedure was adopted for measuring the fading rate for the  
 353 pIR(60)-IRSL(200) and pBL(60)-IRSL(200) signals. For the pIR(60)-IRSL(200)  
 354 signal, an IR bleaching at 60 °C for 200 s was added before the IRSL measurement at  
 355 200 °C for both the regenerative and test dose measurements. The first measurement  
 356 of the pIR(60)-IRSL(200) signal took place at a time  $t_c = 669$  s after the mid-point of

357 the irradiation time. For the pBL(60)-IRSL(200) signal, a BL bleaching at 60 °C for  
358 200 s was added before the IRSL measurement at 200 °C for both the regenerative  
359 and test dose measurements. The first measurement of the pBL(60)-IRSL(200) signal  
360 took place at a time  $t_c = 669$  s after the mid-point of the irradiation time. The decay of  
361 the IRSL at 200 °C, the pIR(60)-IRSL(200) and the pBL(60)-IRSL(200) signals after  
362 normalization as a function of storage time is shown in Fig 10. The corresponding  
363 anomalous fading rates (g-value) are calculated based on the data sets and are also  
364 shown in Fig. 10. It is observed that the IRSL at 200 °C, the pIR(60)-IRSL(200) and  
365 the pBL(60)-IRSL(200) have significantly different laboratory fading rates. The g  
366 value for the IRSL at 200 °C was detected at  $4.0 \pm 0.3$  %/decade, the g value of the  
367 pIR(60)-IRSL(200) was at  $1.6 \pm 0.4$  %/decade and the pBL(60)-IRSL(200) was  $0.4 \pm$   
368  $0.4$  %/decade. This result indicates that there are at least two components for the IRSL  
369 at 200 °C. One component is easy to bleach by IR at 60 °C and BL at 60 °C and it has  
370 higher laboratory fading rate, while the other is hard to bleach by IR at 60 °C and BL  
371 at 60 °C and it has a significantly lower fading rate.

372

#### 373 4. Discussion

374 The sources and process of the traps associated with IRSL from feldspar are  
375 important for developing reliable dating methods. Different models have been  
376 proposed to explain the various luminescence behaviors of feldspars. A single trap  
377 model has been proposed recently to explain the luminescence characteristics for  
378 feldspar (e.g., Jain and Ankjær, 2011; Anderson et al., 2012), while a multi-trap  
379 model is suggested alternatively by others (e.g., Duller and Bøtter-Jensen, 1993; Li  
380 and Li, 2011; Thomsen et al., 2011; Li et al., 2014). These studies were based on their  
381 own experimental designs with limited experimental conditions and the explanations  
382 are based on different assumptions, so a unique interpretation cannot be reached. It is  
383 hoped that the study of the relationship between BLSL and IRSL could be helpful for  
384 understanding the source and process of IRSL, because, unlike IRSL process, BLSL is  
385 expected to be a simpler and delocalized process due to the higher photon energy of

386 BL (~2.64 eV) compared to the main IRSL trap depth (~2.5 eV) (e.g. Baril and  
387 Huntley, 2003; Kars et al., 2013). Based on our results, we are in favor of the  
388 multiple-trap model to explain the experimental data obtained in this study, which  
389 cannot be well explained using a simple single-trap model. The **pieces of evidences**  
390 are given as follows:

391 (1) If we assume that IRSL at 200 °C and 60 °C originate the same traps and then  
392 both signals should be depleted by BL at a similar rate, because BL have energy high  
393 enough to evict the trapped electron to the conduction band and then the electron can  
394 randomly recombine with both close and distant holes. In Fig. 4, it is clearly showned  
395 that, compared with the IRSL at 60 °C, the IRSL at 200 °C is bleached at the  
396 significantly slower rate by BL at 60 °C, suggesting that IRSL signals at 200 °C are  
397 involved with traps which are very hard to bleach by BL at 60 °C. This could be due  
398 to either that the hard-to-bleach component has a deeper trap depth (>2.5 eV) or that  
399 the component has a different photoionization cross-section, which both indicate a  
400 different trap from the easy to bleach component.

401 (2) During the pIR(60)-BLSL(60) experiments, the emitted counts of the IRSL  
402 have a nearly 1:1 relationship with the corresponding lost counts in the pIR-BLSL.  
403 However, this is not the case for the pIR(200)-BLSL(60) (Fig. 3). This indicates that  
404 IRSL at elevated temperature can access more traps that are more difficult to bleach  
405 by BL at 60 °C.

406 (3) The pBL(60)-IRSL(200) and IRSL signals at 200 °C have very different  
407 luminescence properties, such as thermal stability, dose response and fading rate.  
408 Since BL have energy high enough to evict the trapped electron to the conduction  
409 band, the electron will randomly recombine with close or distant holes after excitation.  
410 Hence, BL will cause not only recombination of spatially close electron-hole pairs,  
411 but also recombination of distant electron-hole pairs. As a result, BL bleaching should  
412 not change the relative proportions between close and distant electron-hole pairs.  
413 Correspondingly, it is expected that the pBL-IRSL should have a similar thermal  
414 stability as IRSL, and the pIR-IRSL should have a higher thermal stability than  
415 pBL-IRSL. Our results, however, showed that the pBL(60)-IRSL(200) is significantly

416 more thermally stable than both the IRSL at 200 °C and pIR(60)-IRSL(200) (Fig. 8),  
417 which cannot be explained by the single-trap model. Similarly, a similar fading rate  
418 should be expected for the IRSL(200) and pBL(60)-IRSL(200) signals based on a  
419 single-trap model. For our samples, the g values for the IRSL at 200 °C are greatly  
420 reduced after the BL bleaching at 60 °C for 200 s (Fig. 10). It is interesting to be  
421 noted that the laboratory fading rate of pBL(60)-IRSL(200) is significantly lower than  
422 that of pIR(60)-IRSL(200), suggesting that the BL at 60 °C is more efficiently than  
423 the IR at 60 °C to remove spatially close electron-hole pairs (easy-to-fade), which  
424 cannot be explained by a single trap model.

425 Based on the above arguments, we think that a single trap model is not sufficient  
426 to explain all the luminescence phenomena in feldspar. In the future, it is maybe  
427 helpful to use time-resolved optically stimulated luminescence (TR-OSL) technique  
428 to further study the luminescence behaviors of K-feldspar (e.g. Chithambo and  
429 Galloway, 2001).

430 Another outcome of our study is that we first demonstrate that the  
431 pBL(60)-IRSL(200) has a high thermal stability and a negligible fading rate, which  
432 opens the potential of using this signal in sediments dating without the corrections for  
433 anomalous fading. A potential advantage of using pBL(60)-IRSL(200) is that blue  
434 bleaching at 60 °C can eliminate the contribution of quartz grains to IRSL at  
435 elevated temperatures (Fan et al., 2009). Quartz grains can coexist with K-feldspar  
436 after heavy liquid separation. The IRSL of quartz at elevated temperatures can be  
437 effectively bleached by blue light at low temperatures, but not by infrared. Further  
438 tests on the applicability in dating are required to confirm the suitability of using the  
439 pBL-IRSL at relatively high temperatures.

440

## 441 5. Conclusions

442

443 From the pIR-BLSL and pBL-IRSL bleaching experiments, it is concluded that  
444 the relationship between IRSL and BLSL is dependent on the stimulation temperature.  
445 If stimulation temperatures for the IRSL increase from 60 to 200 °C, at least two

446 components are associated with the IRSL at 200 °C. One component is easy to bleach  
447 by BL at 60 °C, and the other relative hard to bleach by BL at 60 °C. The two  
448 components of the IRSL at 200 °C have significantly different luminescence  
449 properties, in terms of thermal stability, dose saturation level and laboratory fading  
450 rates.

11 Abstract:

12 In optical dating of potassium-feldspar, the luminescence signals can be stimulated  
13 by both infrared (IR) light and blue light (BL). To develop reliable dating methods  
14 using different stimulation light sources for feldspars, it is important to understand the  
15 sources of the traps associated with the infrared stimulated luminescence (IRSL) and  
16 blue light stimulated luminescence (BLSL) and their relationship. In this study, we  
17 explored the luminescence characteristics of IRSL and BLSL at different stimulation  
18 temperatures (from 60 °C to 200 °C) and their relationship based on five sets of  
19 experiments, i.e. post-IR BLSL, post-BL IRSL experiments, pulse annealing test, dose  
20 response test and laboratory fading rate test. Our results suggest that the luminescence  
21 characteristics of IRSL and BLSL and their relationship are dependent on stimulation  
22 temperature. For IR stimulation at a relatively high temperature of 200 °C, at least two  
23 components of IRSL signals are involved in the process. One component of IRSL  
24 signals can be easily bleached by BL stimulation at 60 °C, while the other is relatively  
25 hard to be bleached by BL stimulation at 60 °C. The two components have different  
26 luminescence properties, such as thermal stability, dose response and laboratory fading  
27 rate.

28  
29 Keywords: K-feldspar, IRSL, BLSL, component

---

30  
31 1. Introduction

32

33 Both quartz and potassium-rich feldspar (K-feldspar) have been widely used as  
34 natural dosimeters for optically stimulated luminescence (OSL) dating (Aitken, 1998).  
35 Compared with quartz OSL, the infrared stimulated luminescence (IRSL) signal from  
36 K-feldspar (Hütt et al., 1988) has advantages of much brighter luminescence signals  
37 and much higher dose saturation level, making feldspar as an attractive candidate for  
38 luminescence dating of the natural sedimentary samples. However, the usage of  
39 K-feldspar for dating has long been hindered by the anomalous fading of the trapped  
40 charges related to the IRSL signals (e.g. Spooner, 1994; Huntley and Lamonthé, 2001;  
41 Li and Li, 2008).

42 More recently, progress in understanding anomalous fading in feldspar has raised  
43 the prospect of isolating a non-fading component from the IRSL at relatively high  
44 temperatures (Thomsen et al., 2008; Li, 2010; Jain and Ankjærgaard, 2011; Li and Li,  
45 2013). Correspondingly, a two-step post IR IRSL (pIRIR) protocol (Buylaert et al.,  
46 2009; Thiel et al., 2011) and a multi-elevated-temperature post-IR IRSL (MET-pIRIR)  
47 protocol (Li and Li, 2011a) have been proposed to overcome anomalous fading for  
48 dating K-feldspar from sediments, which offer the promising potential for extending  
49 the luminescence dating limit (Thiel et al., 2011; Li and Li, 2012; Li et al., 2013,  
50 However, the high temperature pIRIR signal (e.g. >200 °C) is found to be more  
51 to bleach than the IRSL signal measured at lower temperatures (Li and Li, 2011a;  
52 Buylaert et al., 2012; Murray et al., 2012), and it usually requires up to several hours  
53 even days of exposure to sunlight or a solar simulator to bleach the pIRIR signal  
54 down to a stable level (here the term “bleach” means to reduce the luminescence  
55 intensity by optical stimulation). For some samples, a significant non-bleachable (or  
56 residual) component in the pIRIR signals was left even after a prolonged bleaching  
57 period using solar simulator or sunlight (Buylaert et al., 2011; Lowick et al., 2012;  
58 Chen et al., 2013; Li et al., 2014b). These studies suggest that the IRSL signals  
59 recorded at relatively high temperature have different luminescence behavior  
60 compared with the IRSL signals at room temperature.

61 There have been several studies conducted to explore the relationship between

62 luminescence with IR stimulation and luminescence with visible wavelength light  
63 stimulation. It was demonstrated that the majority of green light stimulated  
64 luminescence (GLSL) can be bleached by prolonged IR light and an upper limit of ~  
65 90% GLSL was depleted as a result of IR bleaching at room temperature (Duller and  
66 Bøtter-Jensen, 1993; Galloway, 1994). Jain and Singhvi (2001) concluded that the  
67 blue-green (BG) stimulated luminescence measured at 125 °C is associated with at  
68 least two trap populations. One trap population is responsive to both IR stimulation  
69 and BG stimulation. Another trap population is only responsive to BG stimulation.  
70 Gong et al. (2012) conducted a study on the relationship between the infrared  
71 stimulated luminescence (IRSL) and blue light stimulated luminescence (BLSL) at  
72 60 °C. They observed that most of the IRSL signals at 60 °C can be bleached by BL at  
73 60 °C, while the BLSL signals at 60 °C can only be partially bleached by IR at 60 °C.  
74 The sources for the IRSL at 60 °C are mainly associated with the fast and medium  
75 components of the BLSL at 60 °C.

76 In this study, in order to better understand the sources of the traps associated with  
77 the IRSL and BLSL, we further explore the relationship between IRSL and BLSL  
78 using K-feldspar from two aeolian sand samples. The luminescence properties, in  
79 terms of thermal stability, dose response and laboratory fading rate, are also examined  
80 for the different IRSL components at a relatively high temperature of 200 °C.

81

## 82 2. Samples and equipment

83

84 Two aeolian sand samples (HSDK-11 and SY) from the Hunshandake desert in  
85 northeast China were used in this study. Both samples have been investigated in  
86 previous studies (Li et al., 2002; Gong et al., 2013). The samples are from the same  
87 environmental settings of the same region and have similar luminescence behaviors,  
88 so the experimental results obtained from them should be comparable. The samples  
89 were treated with 10 % hydrochloric acid (HCl) and 10 % hydrogen peroxide (H<sub>2</sub>O<sub>2</sub>)  
90 to remove carbonate and organic matter, respectively, in subdued red light in the

91 Luminescence Dating Laboratory, the University of Hong Kong. Grains of 150-180  
92  $\mu\text{m}$  in diameter were obtained by dry sieving. The K-feldspar grains were separated  
93 with heavy liquids ( $2.58 \text{ g}\cdot\text{cm}^{-3}$ ) and then etched for 40 min with diluted (10 %)   
94 hydrofluoric acid (HF) to clean the grains. HCl (10 %) was used again to dissolve any  
95 contaminating fluorides after etching before final rinsing and drying. K-feldspar  
96 grains were prepared by mounting the grains in a monolayer, on a 9.8 mm diameter  
97 aluminum disc with “Silkospay” silicone oil.

98 The luminescence measurements of the sample HSDK-11 were carried out with an  
99 automated Risø TL-DA-15 reader equipped with an IR LED array (880 nm, FWHM  
100 40 nm) and a blue LED array (470 nm, FWHM 20 nm) in the Luminescence Dating  
101 Laboratory, the University of Hong Kong. The IR and BL stimulations deliver  $\sim 135$   
102  $\text{mW}\cdot\text{cm}^{-2}$  and  $\sim 50 \text{ mW}\cdot\text{cm}^{-2}$  at the sample position, respectively (Bøtter-Jensen et al.,  
103 2003). To keep our results comparable with those from Gong et al. (2012), 90% of the  
104 full power was used for stimulation in this study. Irradiations were carried out within  
105 the reader using a  $^{90}\text{Sr}/^{90}\text{Y}$  beta source which delivered a dose rate of  $0.0761 \text{ Gy}\cdot\text{s}^{-1}$  to  
106 K-feldspar on aluminum discs. The IRSL and the BLSL signals were both detected  
107 after passing through 7.5-mm-thick U-340 filters, which mainly pass light from 290  
108 nm to 370 nm with peak transmission at  $\sim 340 \text{ nm}$  (Li et al., 2007b). The experimental  
109 work on the other sample SY was performed in the Luminescence Dating Laboratory,  
110 Institute of Geology and Geophysics, Chinese Academy of Sciences. The  
111 luminescence measurements of the sample SY were carried out with an automated  
112 Risø TL/OSL reader (TL/OSL-DA-15) using the similar equipment setting. The  
113  $^{90}\text{Sr}/^{90}\text{Y}$  beta source in the equipment delivered a dose rate of  $0.0837 \text{ Gy}\cdot\text{s}^{-1}$  to  
114 K-feldspar on aluminum discs.

115

116

### 117 3. Experimental details and results

118

119 3.1 The relationship between the IRSL and the BLSL at different stimulation  
120 temperatures

121 Two sets of experiments, namely post-IR BLSL (pIR-BLSL) and post-blue light  
122 IRSL (pBL-IRSL), are conducted to investigate the relationship between the IRSL and  
123 the BLSL at different stimulation temperatures. For simplification, we describe the  
124 stimulation temperatures used in the prior IR and post-IR BLSL as pIR( $T_1$ )-BLSL( $T_2$ ),  
125 where  $T_1$  is the stimulation temperature used in the prior IR measurement and  $T_2$  is  
126 the temperature used in post-IR BLSL measurement.

127

### 128 3.1.1 pIR-BLSL experiments

129

130 The pIR-BLSL experiments were carried out using the procedure listed in Table 1.  
131 Four aliquots of K-feldspar grains HSDK-11 were firstly heated to 500 °C and then  
132 given a dose of 30.4 Gy. These aliquots were subsequently preheat at 280 °C for 10 s  
133 and then bleached using IR stimulation at a temperature of  $T_1$  for different periods  
134 ranging from 0 to 5000 s. The pIR-BLSL signal ( $L_x$ ) was then measured at a  
135 temperature of  $T_2$ . After that, a test dose of 15.2 Gy was applied and the induced  
136 BLSL signal ( $T_x$ ) was measured following the same preheat to monitor sensitivity  
137 change for  $L_x$ . The signals for both  $L_x$  and  $T_x$  were calculated from the integrated  
138 photon counts in the first 1 s of stimulation, with subtraction of the instrumental  
139 background signal. The experiments are conducted at a set of different temperature  
140 combinations, i.e. pIR(60)-BLSL(60), pIR(100)-BLSL(60), pIR(150)-BLSL(60),  
141 pIR(200)-BLSL(60) and pIR(200)-BLSL(200), respectively.

142 The IR bleaching effects on the pIR-BLSL signal for different periods of time are  
143 shown in Fig. 1. It is observed that the IR bleaching at higher temperatures can  
144 deplete the BLSL at 60 °C at a faster rate than IR stimulation at lower temperatures.  
145 The BLSL at 60 °C was bleached to about 5 % of the initial intensity after IR  
146 bleaching at 200 °C for 5000 s. In comparison, the BLSL at 60 °C was bleached to  
147 about 15 % of the initial intensity after IR bleaching at 60 °C for 5000 s. If we  
148 increase the stimulation temperature in BLSL from 60 to 200 °C, i.e. pIR(200)-BLSL  
149 (200), the IR stimulation at 200 °C can bleach the most of the traps associated with  
150 the BLSL at 200 °C and only 6 % of the initial intensity of the BLSL at 200 °C was

151 remaining after IR bleaching at 200 °C for 5000 s (Fig. 1). The results suggest that  
152 both the BLSL measured at 60 °C and the BLSL at 200 °C can only be partially  
153 bleached by prolonged (up to 5000 s) IR stimulation even at a relatively high  
154 temperature (i.e. 200 °C).

155 In our previous study (Gong et al., 2012), it was found that the BLSL signals  
156 measured at 60 °C for the K-feldspar from sample HSDK-11 can be described using  
157 three first-order exponential components, which are termed as fast (F), medium (M)  
158 and slow (S) components. Gong et al. (2012) demonstrated that the sources for the  
159 IRSL at 60 °C are mainly associated with the fast and medium components of the  
160 BLSL at 60 °C. To further demonstrate the relationship between IRSL signal at  
161 relatively high temperatures and BLSL at 60 °C, the residual BLSL at 60 °C after IR  
162 bleaching for different time from 0 s to 5000 s were then fitted using three OSL  
163 components. It is found that the pIR-BLSL signals can be well described by the three  
164 exponential functions (all  $R^2 > 0.96$ ). The relative ratios of the decay rates of the  
165 components of BLSL at 60 °C, i.e.  $b_f/b_m$  and  $b_m/b_s$ , are calculated at  $4.87 \pm 0.14$  and  
166  $10.69 \pm 0.41$ , respectively (here the parameters of  $b_f$ ,  $b_m$  and  $b_s$  refer to the decay rate  
167 of the fast, medium and slow components of BLSL at 60 °C, respectively). It is noted  
168 that the assumption of that the BLSL process is first-order may not be true. However,  
169 this will not influence our conclusion because it is the relationship between the  
170 different parts of BLSL (represented by the fast, medium and slow components) and  
171 IRSL that is crucial for our study, rather than whether these components are first-order  
172 or not. We, however, acknowledge that there may be some uncertainty associated with  
173 the fitting and some results demonstrated by Fig. 2 and Fig. 6 might be partially  
174 influenced if these components are not first-order.

175 Fig. 2a illustrates four representative pIR-BLSL signals, which are fitted into three  
176 components. The results of IR bleaching for the fast, medium and slow component of  
177 BLSL at 60 °C are shown in Fig. 2b. It is observed that the IR stimulation at 200 °C  
178 for 5000 s can deplete 99 % of the fast component, ~99 % of the medium component  
179 but only ~38 % of the slow component for the BLSL at 60 °C, while IR stimulation at  
180 60 °C for 5000 s can only deplete ~97 % of fast component, ~91 % of medium

181 component and ~12 % of slow component, respectively, for the BLSL at 60 °C. These  
182 results indicate that IRSL obtained at 200 °C involves more traps associated with  
183 hard-to-bleach components (i.e. the medium and slow components) of BLSL at 60 °C  
184 than does the IR stimulation at 60 °C. The results are consistent with previous studies  
185 that the IRSL signals at high temperatures (e.g. >200 °C) are relatively harder to  
186 bleach than the IRSL at 60 °C (Buylaert et al., 2011; Li and Li, 2011a; Chen et al.,  
187 2013).

188 The relationship between the IRSL and BLSL at different temperatures is further  
189 studied by investigating the relationship between the emitted light counts from the  
190 IRSL and the corresponding lost counts obtained from the pIR( $T_1$ )-BLSL( $T_2$ )  
191 experiments ( $T_1$ = 60, 100, 150, 200 °C;  $T_2$ = 60, 200 °C). This is similar to the method  
192 applied to study the relation between IRSL and thermoluminescence (TL) by Duller  
193 (1995). In Fig. 3, we plot the emitted counts from the IRSL, against the corresponding  
194 lost counts of the pIR-BLSL as a result of IR bleaching. It is observed that, if the  
195 stimulation temperature for IR and BL was identical in both cases (i.e.  
196 pIR(60)-BLSL(60) and pIR(200)-BLSL(200)), the emitted counts of the IRSL have a  
197 nearly 1:1 relationship with the corresponding lost counts in the pIR-BLSL. However,  
198 in the case of  $T_1 > T_2$ , the emitted counts of the IRSL are larger than the corresponding  
199 lost counts in pIR-BLSL, indicating that the relationship between BLSL and IRSL is  
200 dependent on the stimulation temperature. It is to be noted that such a relationship  
201 between IRSL and BLSL is not influenced by the interference of isothermal TL,  
202 because the preheat at 280 °C for 10 s is sufficient to remove any isothermal TL at  
203 200 °C. One straightforward explanation for the temperature dependency of the  
204 relationship is that at least two components are involved in the IRSL at the relatively  
205 high temperature (such as the IRSL at 200 °C). One component is responsive to the  
206 BL at 60 °C. The other is hard to reach by BL at 60 °C, but can be accessed at higher  
207 temperatures. The results further support fact that the IRSL signals at relatively high  
208 temperatures are relatively harder to bleach than the IRSL at 60 °C (e.g. Chen et al.,  
209 2013).

210

### 211 3.1.2 pBL-IRSL experiments

212

213 The effects of BL bleaching at 60 °C and 200 °C on the IRSL signals at different  
214 temperatures (60, 100, 150 and 200 °C) are investigated using pBL-IRSL experiments  
215 (see the procedures listed in Table 1). The experiments conducted are  
216 pBL(60)-IRSL(60), pBL(60)-IRSL(100), pBL(60)-IRSL(150), pBL(60)-IRSL(200)  
217 and pBL(200)-IRSL(200), respectively. Four aliquots of K-feldspar grains of  
218 HSDK-11 were firstly heated to 500 °C to remove any residual signals and then given  
219 the same irradiation dose of 30.4 Gy. These aliquots were then held at 280 °C for 10 s.  
220 They were subsequently bleached with BL at 60, 200 °C for different periods from 0  
221 to 320 s before IRSL measurements. After that, the IRSL sensitivity was monitored  
222 and measured following a test dose of 15.2 Gy and preheat at 280 °C for 10 s.

223 The remnant IRSL at different temperatures (50, 100, 150 200 °C) as a result of  
224 BL bleaching at 60, 200 °C for different periods of time are shown in Fig. 4. It is  
225 demonstrated that the IRSL at 60 °C can be bleached to a negligible level (~0.2 %) by  
226 BL stimulation at 60 °C for 320 s, while 3.5 % of the initial IRSL at 200 °C still  
227 remains after BL bleaching at 60 °C for 320 s. These results indicate that, compared  
228 with the IRSL at 60 °C, the IRSL at 200 °C involves more traps that are harder to  
229 bleach by BL at 60 °C. However, the IRSL at 200 °C can be bleached to a negligible  
230 level (~0.2 %) by BL stimulation at 200 °C for 320 s. In addition, the decay rates in  
231 the pBL(200)-IRSL (200) and the pBL(60)-IRSL(60) are very similar and they are  
232 calculated at  $0.23 \pm 0.02 \text{ s}^{-1}$  and  $0.21 \pm 0.01 \text{ s}^{-1}$ , respectively. These results further  
233 suggest that the relationship between the IRSL and the BLSL is dependent on  
234 stimulation temperature.

235 Further investigation is made on the relationship between the emitted counts from  
236 the BLSL and the corresponding lost counts from pBL( $T_1$ )-IRSL( $T_2$ ) ( $T_1= 60, 200 \text{ °C}$ ;  
237  $T_2= 60, 100, 150, 200 \text{ °C}$ ) (Fig. 5). It is observed that the emitted counts from the  
238 BLSL measured both at 60 °C and at 200 °C are significantly larger than the  
239 corresponding lost counts from pBL( $T_1$ )-IRSL( $T_2$ ). These results indicate that BL can

240 access much more traps than IR stimulation. Only part of traps associated with the  
241 BLSL at 60 °C and at 200 °C is accessible by IR stimulation, which is similar to the  
242 results of IRSL observed at 60 °C (Gong et al, 2012). It is also demonstrated that  
243 relationship between emitted BLSL counts and lost counts of pBL-IRSL changes as  
244 the stimulation temperature changes.

245 To further demonstrate the relationship between different OSL components of the  
246 BLSL signal at 60 °C and the IRSL signals at relatively high temperatures, the emitted  
247 light counts from different OSL components of the BLSL signal at 60 °C are  
248 compared with the corresponding lost counts from the pBL(60)-IRSL(200) and  
249 pBL(60)-IRSL(60) as a result of BL bleaching at 60 °C for different periods. We plot  
250 the emitted counts from the various OSL components of the BLSL at 60 °C, against  
251 the lost counts of IRSL at 60 °C and IRSL at 200 °C as a result of BL bleaching in Fig.  
252 6. It is observed that the lost counts in pBL(60)-IRSL(200) are larger than the sum of  
253 the emitted light counts of the fast and medium components of BLSL at 60 °C, while  
254 the lost counts in pBL(60)-IRSL(60) have a nearly 1:1 relationship with the sum of  
255 the emitted light counts of the fast and medium components of BLSL at 60 °C. These  
256 results indicate that the IRSL signals at 200 °C are involved with not only the fast and  
257 medium components of BLSL at 60 °C, but also some other OSL components (e.g.  
258 slower components of BLSL at 60 °C). In contrast, there is a close relationship  
259 between IRSL at 60 °C and the fast and medium components of BLSL at 60 °C (Gong  
260 et al., 2012). The results are consistent with the observations in previous section 3.1.1.

261 In summary, the results from the pIR-BLSL and pBL-IRSL bleaching experiments  
262 suggest that the relationship between IRSL and BLSL is dependent on stimulation  
263 temperature. At least two components of traps are involved in the IRSL measured at  
264 elevated temperatures (e.g., 200 °C). One component can be easily bleached by BL at  
265 60 °C, and the other of the IRSL is relatively harder to access by BL at 60 °C. The  
266 results show that the IRSL signals at relatively high temperatures are harder to be  
267 bleached than the IRSL at room temperature.

268

269 3.2 Luminescence properties of IRSL at relatively high temperature

270

271 The luminescence characteristics of the IRSL at 200 °C, the pIR(60)-IRSL(200)  
272 and the pBL(60)-IRSL(200), including thermal stability, dose response and laboratory  
273 fading rate, were further investigated. In both the pIR(60)-IRSL(200) and the  
274 pBL(60)-IRSL(200) experiments, the IR and BL bleaching time was both fixed at 200  
275 s.

276

### 277 3.2.1 Thermal stability study

278

279 The thermal stability studies are carried out using the pulse annealing test (Table 2)  
280 (Li et al., 1997; Li and Tso, 1997). The tests were conducted for the IRSL at 60 °C,  
281 the IRSL at 200 °C, the pIR(60)-IRSL(200) and the pBL(60)-IRSL(200), respectively.  
282 An aliquot of K-feldspar of SY was firstly heated to 500 °C and then given an  
283 irradiation dose of 30.4 Gy. After that, it was preheated at 280 °C for 10 s and then  
284 heated to a temperature at T °C before the remaining IRSL was measured at 60 °C for  
285 160 s. The sensitivity change was monitored by measuring the IRSL signal at 60 °C  
286 from a test dose of 30.4 Gy. The same preheat condition (280 °C for 10 s) was applied  
287 for the test dose IRSL measurement. This cycle was repeated by increasing the  
288 annealing temperature (T) from 160 °C to 500 °C in steps of 20 °C. The similar pulse  
289 annealing test procedures were also conducted for the IRSL at 200 °C, the  
290 pIR(60)-IRSL(200) and the pBL(60)-IRSL(200) (Table 2). The heating rate for all  
291 these pulse annealing experiments was 3 °C·s<sup>-1</sup>.

292 The typical decay curve of the pBL(60)-IRSL(200) signal is shown in Fig. 7. The  
293 results of the pulse annealing test of the IRSL at 60 °C, the IRSL at 200 °C, the  
294 pIR(60)-IRSL(200) and the pBL(60)-IRSL(200) are shown in Fig. 8. It is observed  
295 that the thermal stability of the IRSL at 200 °C is relatively more stable than that of  
296 the IRSL at 60 °C. Li and Li (2011b; 2013) also observed the different thermal  
297 stabilities among the IRSL at different stimulation temperatures. In addition, it is  
298 found that both pIR(60)-IRSL(200) and pBL(60)-IRSL(200) is more thermally stable  
299 than IRSL at 200 °C. The results suggest that at least two components are involved in

300 the IRSL at 200 °C and the components have significantly different thermal stability.  
301 Both IR at 60 °C and BL at 60 °C can remove the thermally relatively unstable  
302 component of IRSL 200 °C. It is interesting to be noted that the pBL(60)-IRSL(200)  
303 is significantly more thermally stable than pIR(60)-IRSL(200), indicating that the BL  
304 at 60 °C is more efficient than IR at 60 °C to reduce thermally unstable component in  
305 the IRSL at 200 °C.

306

### 307 3.2.2 Dose response curves

308

309 Different shapes of dose response curve (DRC) may provide an indication of  
310 different origins of different luminescence signals (Gong et al., 2012). Here we  
311 compare the DRC of the IRSL at 200 °C from K-feldspar with that of the  
312 pBL(60)-IRSL(200). Regenerative doses ranging from 0 to 1950 Gy were employed  
313 in a single aliquot regeneration (SAR) protocol for the IRSL at 200 °C. A test dose of  
314 52 Gy was applied and the test dose signal ( $T_x$ ) was measured to monitor and correct  
315 for sensitivity change. A recycle dose at 26 Gy was used and the recycling ratios all  
316 fall within the range of  $1.0 \pm 0.05$  for the sample. The preheat temperature (held at  
317 280 °C for 10 s) was the same for regeneration and test dose measurements. A  
318 cut-heat to 500 °C was used between each of the SAR cycles to clean the residual  
319 signals from the previous cycle. The IRSL signals  $L_x$  and  $T_x$  were calculated from the  
320 integrated photon counts in the first 1 s of stimulation, with subtraction of a  
321 background signal derived from the last 10 s of the 160 s stimulation. For construction  
322 the DRC of the pBL(60)-IRSL(200), a similar SAR procedure was applied, except  
323 that a BL bleaching at 60 °C for 200 s was added before each IRSL measurement for  
324 both the regenerative and test dose measurements. The dose response curves for the  
325 two signals are shown in Fig. 9. It is found that the pBL(60)-IRSL(200) signal have a  
326 different dose saturation level with the IRSL at 200 °C.

327 If the two dose response curves are fitted with double saturation exponential  
328 function (equation 1),

329 
$$I = I_0 + I_a(1 - \exp(-D/D_{0,a})) + I_b(1 - \exp(-D/D_{0,b})) \quad (1)$$

330 The dose saturation level of two  $D_0$  ( $D_{0,a}$  and  $D_{0,b}$ ) parameters are  $42.9 \pm 5.8$  Gy  
 331 and  $289.7 \pm 22.4$  Gy for the pBL(60)-IRSL(200) signal, while the values of two  $D_0$   
 332 ( $D_{0,a}$  and  $D_{0,b}$ ) parameters of the IRSL at 200 °C are significantly higher at  $214.6 \pm 9.9$   
 333 Gy and  $806.1 \pm 69.6$  Gy, respectively. The results indicate that at least two components  
 334 are involved in the IRSL at elevated temperature. One group is easy to bleach by BL  
 335 at 60 °C and they have a higher dose saturation level, while the other group is hard to  
 336 bleach by BL at 60 °C and they have a lower dose saturation level.

337

### 338 3.2.3 Laboratory fading test

339

340 Anomalous fading was observed for both IRSL and BLSL signals in previous  
 341 studies (e.g. Thomsen et al., 2008). Here we studied the laboratory fading rates for the  
 342 IRSL at 200 °C, the pIR(60)-IRSL(200) and the pBL(60)-IRSL(200) signals. In  
 343 measurement of the IRSL at 200 °C, six aliquots of SY were heated to 500 °C to  
 344 remove any residual signals (similar to a hot-bleach between SAR cycles). Then these  
 345 aliquots were given 50.8 Gy and immediately preheated at 280 °C for 10 s. The  
 346 sensitivity corrected signals were then measured after delays of different periods. For  
 347 the test dose, 12.7 Gy was given and the same preheat condition was applied. The  
 348 IRSL signals  $L_{(x)}$  and  $T_{(x)}$  were calculated from the integrated photon counts in the  
 349 first 1 s of stimulation, with subtraction of a background signal derived from the last  
 350 10 s of the 160 s stimulation. The first measurement of the IRSL at 200 °C signal took  
 351 place at a time  $t_c = 562$  s after the mid-point of the irradiation time. A similar  
 352 measurement procedure was adopted for measuring the fading rate for the  
 353 pIR(60)-IRSL(200) and pBL(60)-IRSL(200) signals. For the pIR(60)-IRSL(200)  
 354 signal, an IR bleaching at 60 °C for 200 s was added before the IRSL measurement at  
 355 200 °C for both the regenerative and test dose measurements. The first measurement  
 356 of the pIR(60)-IRSL(200) signal took place at a time  $t_c = 669$  s after the mid-point of

357 the irradiation time. For the pBL(60)-IRSL(200) signal, a BL bleaching at 60 °C for  
358 200 s was added before the IRSL measurement at 200 °C for both the regenerative  
359 and test dose measurements. The first measurement of the pBL(60)-IRSL(200) signal  
360 took place at a time  $t_c = 669$  s after the mid-point of the irradiation time. The decay of  
361 the IRSL at 200 °C, the pIR(60)-IRSL(200) and the pBL(60)-IRSL(200) signals after  
362 normalization as a function of storage time is shown in Fig 10. The corresponding  
363 anomalous fading rates (g-value) are calculated based on the data sets and are also  
364 shown in Fig. 10. It is observed that the IRSL at 200 °C, the pIR(60)-IRSL(200) and  
365 the pBL(60)-IRSL(200) have significantly different laboratory fading rates. The g  
366 value for the IRSL at 200 °C was detected at  $4.0 \pm 0.3$  %/decade, the g value of the  
367 pIR(60)-IRSL(200) was at  $1.6 \pm 0.4$  %/decade and the pBL(60)-IRSL(200) was  $0.4 \pm$   
368  $0.4$  %/decade. This result indicates that there are at least two components for the IRSL  
369 at 200 °C. One component is easy to bleach by IR at 60 °C and BL at 60 °C and it has  
370 higher laboratory fading rate, while the other is hard to bleach by IR at 60 °C and BL  
371 at 60 °C and it has a significantly lower fading rate.

372

#### 373 4. Discussion

374 The sources and process of the traps associated with IRSL from feldspar are  
375 important for developing reliable dating methods. Different models have been  
376 proposed to explain the various luminescence behaviors of feldspars. A single trap  
377 model has been proposed recently to explain the luminescence characteristics for  
378 feldspar (e.g., Jain and Ankjærgaard, 2011; Anderson et al., 2012), while a multi-trap  
379 model is suggested alternatively by others (e.g., Duller and Bøtter-Jensen, 1993; Li  
380 and Li, 2011; Thomsen et al., 2011; Li et al., 2014). These studies were based on their  
381 own experimental designs with limited experimental conditions and the explanations  
382 are based on different assumptions, so a unique interpretation cannot be reached. It is  
383 hoped that the study of the relationship between BLSL and IRSL could be helpful for  
384 understanding the source and process of IRSL, because, unlike IRSL process, BLSL is  
385 expected to be a simpler and delocalized process due to the higher photon energy of

386 BL (~2.64 eV) compared to the main IRSL trap depth (~2.5 eV) (e.g. Baril and  
387 Huntley, 2003; Kars et al., 2013). Based on our results, we are in favor of the  
388 multiple-trap model to explain the experimental data obtained in this study, which  
389 cannot be well explained using a simple single-trap model. The pieces of evidence are  
390 given as follows:

391 (1) If we assume that IRSL at 200 °C and 60 °C originate the same traps and then  
392 both signals should be depleted by BL at a similar rate, because BL have energy high  
393 enough to evict the trapped electron to the conduction band and then the electron can  
394 randomly recombine with both close and distant holes. In Fig. 4, it is clearly shown  
395 that, compared with the IRSL at 60 °C, the IRSL at 200 °C is bleached at the  
396 significantly slower rate by BL at 60 °C, suggesting that IRSL signals at 200 °C are  
397 involved with traps which are very hard to bleach by BL at 60 °C. This could be due  
398 to either that the hard-to-bleach component has a deeper trap depth (>2.5 eV) or that  
399 the component has a different photoionization cross-section, which both indicate a  
400 different trap from the easy to bleach component.

401 (2) During the pIR(60)-BLSL(60) experiments, the emitted counts of the IRSL  
402 have a nearly 1:1 relationship with the corresponding lost counts in the pIR-BLSL.  
403 However, this is not the case for the pIR(200)-BLSL(60) (Fig. 3). This indicates that  
404 IRSL at elevated temperature can access more traps that are more difficult to bleach  
405 by BL at 60 °C.

406 (3) The pBL(60)-IRSL(200) and IRSL signals at 200 °C have very different  
407 luminescence properties, such as thermal stability, dose response and fading rate.  
408 Since BL have energy high enough to evict the trapped electron to the conduction  
409 band, the electron will randomly recombine with close or distant holes after excitation.  
410 Hence, BL will cause not only recombination of spatially close electron-hole pairs,  
411 but also recombination of distant electron-hole pairs. As a result, BL bleaching should  
412 not change the relative proportions between close and distant electron-hole pairs.  
413 Correspondingly, it is expected that the pBL-IRSL should have a similar thermal  
414 stability as IRSL, and the pIR-IRSL should have a higher thermal stability than  
415 pBL-IRSL. Our results, however, showed that the pBL(60)-IRSL(200) is significantly

416 more thermally stable than both the IRSL at 200 °C and pIR(60)-IRSL(200) (Fig. 8),  
417 which cannot be explained by the single-trap model. Similarly, a similar fading rate  
418 should be expected for the IRSL(200) and pBL(60)-IRSL(200) signals based on a  
419 single-trap model. For our samples, the  $g$  values for the IRSL at 200 °C are greatly  
420 reduced after the BL bleaching at 60 °C for 200 s (Fig. 10). It is interesting to be  
421 noted that the laboratory fading rate of pBL(60)-IRSL(200) is significantly lower than  
422 that of pIR(60)-IRSL(200), suggesting that the BL at 60 °C is more efficiently than  
423 the IR at 60 °C to remove spatially close electron-hole pairs (easy-to-fade), which  
424 cannot be explained by a single trap model.

425 Based on the above arguments, we think that a single trap model is not sufficient  
426 to explain all the luminescence phenomena in feldspar. In the future, it is maybe  
427 helpful to use time-resolved optically stimulated luminescence (TR-OSL) technique  
428 to further study the luminescence behaviors of K-feldspar (e.g. Chithambo and  
429 Galloway, 2001).

430 Another outcome of our study is that we first demonstrate that the  
431 pBL(60)-IRSL(200) has a high thermal stability and a negligible fading rate, which  
432 opens the potential of using this signal in sediments dating without the corrections for  
433 anomalous fading. A potential advantage of using pBL(60)-IRSL(200) is that blue  
434 bleaching at 60 °C can eliminate the contribution of quartz grains to IRSL at elevated  
435 temperatures (Fan et al., 2009). Quartz grains can coexist with K-feldspar after heavy  
436 liquid separation. The IRSL of quartz at elevated temperatures can be effectively  
437 bleached by blue light at low temperatures, but not by infrared. Further tests on the  
438 applicability in dating are required to confirm the suitability of using the pBL-IRSL at  
439 relatively high temperatures.

440

## 441 5. Conclusions

442

443 From the pIR-BLSL and pBL-IRSL bleaching experiments, it is concluded that  
444 the relationship between IRSL and BLSL is dependent on the stimulation temperature.  
445 If stimulation temperatures for the IRSL increase from 60 to 200 °C, at least two

446 components are associated with the IRSL at 200 °C. One component is easy to bleach  
447 by BL at 60 °C, and the other relative hard to bleach by BL at 60 °C. The two  
448 components of the IRSL at 200 °C have significantly different luminescence  
449 properties, in terms of thermal stability, dose saturation level and laboratory fading  
450 rates.

451

## 452 Acknowledgments

453 This study was financially supported by the grants to Sheng-Hua Li from the  
454 Research Grant Council of the Hong Kong Special Administrative Region, China  
455 (Project nos. 7028/08P and 7033/12P). The authors are grateful to the two anonymous  
456 reviewers for providing valuable comments and suggestions on the manuscript.

594

595 Figure 1: Remnant BLSL measured at 60 °C and 200 °C after IR bleaching at  
596 different temperature for different times. The temperatures for IR bleaching were set  
597 at 60, 100, 150 and 200 °C, respectively.

598

599 Figure 2: (a) four representative pIR-BLSL signals, which are then deconvoluted into  
600 three components. For each of the fitting, the F-statistics are provided and they are all  
601 significantly larger than  $F_{0.01}$  (e.g. Adamiec, 2005). The corresponding residuals are  
602 shown at the right. (b) The residual fast, medium and slow components of BLSL at  
603 60 °C after IR bleaching for different time from 0 s to 5000 s. To better demonstrate  
604 the data, the residual fast and medium components of BLSL at 60 °C after IR  
605 bleaching for different time from 0 s to 320 s were further shown in the insets, while  
606 the y-axis in the insets is on the logarithmic scale. The data were from sample  
607 HSDK-11 and the fast, medium and slow components of BLSL at 60 °C were fitted  
608 with the decay rates of  $0.375 \pm 0.004 \text{ s}^{-1}$ ,  $0.077 \pm 0.002 \text{ s}^{-1}$  and  $0.0072 \pm 0.0002 \text{ s}^{-1}$ ,  
609 respectively, the same as Gong et al. (2012).

610

611 Figure 3: The relationship between emitted counts of the IRSL and the corresponding  
612 lost counts of pIR( $T_1$ )-BLSL( $T_2$ ) as a result of IR bleaching for different time.  $T_1 = 60,$   
613  $100, 150, 200 \text{ °C}$ ,  $T_2 = 60, 200 \text{ °C}$  respectively.

614

615 Figure 4: Remnant IRSL after blue light bleaching at 60 °C and 200 °C for different  
616 times. The temperatures for IR stimulations were set at 60, 100, 150 and 200 °C,  
617 respectively.

618

619 Figure 5: The relationship between emitted counts of the BLSL and the corresponding  
620 lost counts of pBL( $T_1$ )-IRSL( $T_2$ ) as a result of blue light bleaching for different time.  
621  $T_1 = 60, 200 \text{ °C}$ ,  $T_2 = 60, 100, 150, 200 \text{ °C}$ , respectively.

622

623 Figure 6: The relationship between emitted counts of OSL components of BLSL at  
624 60 °C and the lost counts of pBL(60)-IRSL(200) and pBL(60)-IRSL(60) as a result of  
625 blue light bleaching at 60 °C for different times. F+M: The sum of fast and medium  
626 components of the BLSL at 60 °C; S: slow component of the BLSL at 60 °C. The data  
627 were from sample HSDK-11.

628

629 Figure 7: The typical decay curves of the pBL(60)-IRSL(200) from sample HSDK-11.  
630 All the signals were normalized using the initial intensity of the pBL(60)-IRSL( 200).

631

632 Figure 8: Pulse annealing curves based on the IRSL signal at 60 °C, the IRSL signal at  
633 200 °C, pIR(60)-IRSL(200) and the pBL(60)-IRSL(200) signal; In the  
634 pIR(60)-IRSL(200) and pBL(60)-IRSL(200) experiments, the previous IR stimulation  
635 and BL stimulation at 60 °C are both at 200 s. The heating rate was 3 °C·s<sup>-1</sup>.

636

637 Figure 9: Dose response curves of the IRSL signal at 200 °C and the  
638 pBL(60)-IRSL(200) signal. The two dose response curves could be fitted well by the  
639 double saturation exponential function ( $R^2 > 0.99$ ; residuals are shown in the inset).

640

641 Figure 10: Anomalous fading tests for IRSL signal at 200 °C, the pIR(60)-IRSL(200)  
642 and the pBL(60)-IRSL(200) signal using six aliquots from sample SY as a function of  
643 delayed period (t).

902 60 °C is steps 1, 2, 3, 4, 5a, 6, 7, 8a and 9, the sequence of IRSL at 200 °C is steps 1,  
903 2, 3, 4, 5b, 6, 7, 8b and 9, the sequence of pIR(60)-IRSL(200) is steps 1, 2, 3, 3a, 4, 5b,  
904 6, 7, 8b and 9 and the sequence of pBL(60)-IRSL(200) is steps 1, 2, 3, 3b, 4, 5b, 6, 7,  
905 8b and 9.

906

907

Step	Treatment	Observed
(1)	Cut-heat to 500 °C	
(2)	Regenerative dose (30.4 Gy)	
(3)	Preheat to 280 °C for 10 s	
(3a)	IR bleaching at 60 °C for 200 s	
(3b)	BL bleaching at 60 °C for 200 s	
(4)	Cut-heat to T °C (160 °C -500 °C)	
(5a)	IRSL measurement at 60 °C for 160 s	$L_{(IRSL\ 60\ ^\circ C)}$
(5b)	IRSL measurement at 200 °C for 160 s	$L_{(IRSL\ 200\ ^\circ C)}$
(6)	Test dose (30.4 Gy)	
(7)	Preheat to 280 °C for 10 s	
(8a)	IRSL measurement at 60 °C for 160 s	$T_{(IRSL\ 60\ ^\circ C)}$
(8b)	IRSL measurement at 200 °C for 160 s	$T_{(IRSL\ 200\ ^\circ C)}$
(9)	Return to step 1 and $T = T + 20\ ^\circ C$
