Measurement of the $W^\pm Z$ boson pair-production cross section in $pp$ collisions at $\sqrt{s} = 13$ TeV with the ATLAS detector

The ATLAS Collaboration

1. Introduction

The production of $W^\pm Z$ pairs in hadron collisions is an important test of the electroweak sector of the Standard Model (SM). The $W^\pm Z$ final states arise from two vector bosons radiated by quarks or from the decay of a virtual $W$ boson into a $W^\pm Z$ pair, which involves a triple gauge coupling (TGC). In addition, $W^\pm Z$ pairs can be produced in vector-boson scattering processes, which involve triple and quartic gauge couplings (QGC) and are sensitive to the electroweak symmetry breaking sector of the SM. New physics could manifest in $W^\pm Z$ final states as a modification of the TGC and QGC strength. Precise knowledge of the $W^\pm Z$ production cross section is therefore necessary in the search for new physics.

Measurements of the $W^\pm Z$ production cross section in proton–antiproton collisions at a centre-of-mass energy of $\sqrt{s} = 1.96$ TeV were published by the CDF and D0 Collaborations [1,2] using integrated luminosities of 7.1 fb$^{-1}$ and 8.6 fb$^{-1}$, respectively. At the Large Hadron Collider (LHC), measurements have been performed in proton–proton ($pp$) collisions by the ATLAS Collaboration [3,4] at $\sqrt{s} = 7$ TeV and 8 TeV using integrated luminosities of 4.6 fb$^{-1}$ and 20.3 fb$^{-1}$, respectively.

This Letter presents measurements of the $W^\pm Z$ production cross section in $pp$ collisions at a centre-of-mass energy of $\sqrt{s} = 13$ TeV. The data sample analysed was collected in 2015 by the ATLAS experiment at the LHC, and corresponds to an integrated luminosity of 3.2 fb$^{-1}$. The $W$ and $Z$ bosons are reconstructed using their decay modes into electrons or muons. The inclusive cross section in the detector fiducial region for leptonic decay modes is $\sigma_{\text{fid}}^{W^\pm Z} = 63.2 \pm 3.2\,(\text{stat.}) \pm 2.6\,(\text{sys.}) \pm 1.5\,(\text{lumi.})$ fb. In comparison, the next-to-leading-order Standard Model prediction is $53.4^{+5.7}_{-5.0}$ fb. The extrapolation of the measurement from the fiducial to the total phase space yields $\sigma_{\text{tot}}^{W^\pm Z} = 50.6 \pm 2.6\,(\text{stat.}) \pm 2.0\,(\text{sys.}) \pm 0.9\,(\text{th.}) \pm 1.2\,(\text{lumi.})$ pb, in agreement with a recent next-to-next-to-leading-order calculation of $48.2^{+1.6}_{-1.5}$ pb. The cross section as a function of jet multiplicity is also measured, together with the charge-dependent $W^+ Z$ and $W^- Z$ cross sections and their ratio.

$^1$ ATLAS uses a right-handed coordinate system with its origin at the nominal interaction point (IP) in the centre of the detector and the z-axis along the beam axis.
sion point is surrounded by inner tracking detectors (collectively referred to as the inner detector), followed by a superconducting solenoid providing a 2 T axial magnetic field, a calorimeter system and a muon spectrometer.

The inner detector (ID) provides precise measurements of charged-particle tracks in the pseudorapidity range $|\eta| < 2.5$. It consists of three subdetectors arranged in a coaxial geometry around the beam axis: a silicon pixel detector, a silicon microstrip detector and a transition radiation tracker. The newly installed innermost layer of pixels sensors [9,10] was operational for the first time during the 2015 data taking.

The electromagnetic calorimeter covers the region $|\eta| < 3.2$ and is based on a high-granularity, lead/liquid-argon (LAr) sampling technology. The hadronic calorimeter uses a steel/scintillator-tile detector in the region $|\eta| < 1.7$ and a copper/LAr detector in the region $1.5 < |\eta| < 3.2$. The most forward region of the detector, $3.1 < |\eta| < 4.9$, is equipped with a forward calorimeter, measuring electromagnetic and hadronic energies in copper/LAr and tungsten/LAr modules.

The muon spectrometer (MS) comprises separate trigger and high-precision tracking chambers to measure the deflection of muons in a magnetic field generated by three large superconducting toroids arranged with an eightfold azimuthal coil symmetry around the calorimeters. The high-precision chambers cover a range of $|\eta| < 2.7$. The muon trigger system covers the range $|\eta| < 2.4$ with resistive-plate chambers in the barrel and thin-gap chambers in the endcap regions.

A two-level trigger system is used to select events in real time. It consists of a hardware-based first-level trigger and a software-based high-level trigger. The latter employs algorithms similar to those used offline to identify electrons, muons, photons and jets.

3. Phase space definition

The fiducial phase space used to measure the $W^\pm Z$ cross section is defined to closely follow the criteria used to define the signal region described in Section 5. The phase space is based on the kinematics of the final-state leptons associated with the $W$ and $Z$ boson decays. Leptons produced in the decay of a hadron, a $\tau$ or their descendants are not considered in the definition of the fiducial phase space. In the simulation, the kinematics of the charged lepton after quantum electrodynamics (QED) final-state radiation (FSR) are “dressed” at particle level by including contributions from photons with an angular distance $\Delta \phi = \sqrt{(\Delta \eta)^2 + (\Delta \phi)^2} < 0.1$ from the lepton. Dressed leptons, and final-state neutrinos that do not originate from hadron or $\tau$ decays, are matched to the $W$ and $Z$ boson decay products using a Monte Carlo generator-independent algorithmic approach, called the “resonant shape” algorithm [4], that takes into account the nominal line shapes of the $W$ and $Z$ resonances.

The reported cross sections are measured in a fiducial phase space defined at particle level by the following requirements: the transverse momentum $p_T$ of the dressed leptons from the $Z$ boson decay is above 15 GeV, the $p_T$ of the charged lepton from the $W$ decay is above 20 GeV, the absolute value of the pseudorapidity of the charged leptons from the $W$ and $Z$ bosons is below 2.5, the invariant mass of the two leptons from the $Z$ boson decay differs at most by 10 GeV from the world average value of the $Z$ boson mass $m_{Z}^{\text{PDG}}$ [11]. The $W$ transverse mass, defined as

$$m_W^T = \sqrt{2 \cdot p_T^L \cdot p_T^\nu \cdot [1 - \cos \Delta \phi (\ell, \nu)]},$$

where $\Delta \phi (\ell, \nu)$ is the angle between the lepton and the neutrino in the transverse plane, is required to be above 30 GeV. In addition, it is required that the angular distance $\Delta R$ between the charged leptons from the $W$ and $Z$ decay is larger than 0.3, and that $\Delta R$ between the two leptons from the $Z$ decay is larger than 0.2.

The fiducial cross section is extrapolated to the total phase space and corrected for the leptonic branching fractions of the $W$ and $Z$ bosons. The total phase space is defined by requiring the invariant mass of the lepton pair associated with the $Z$ boson to be in the range $66 < m_{\ell\ell} < 116$ GeV.

For the jet multiplicity differential measurement, particle-level jets are reconstructed from stable particles with a lifetime of $\tau > 30$ ps in the simulation after parton showering, hadronisation, and decay of particles with $\tau < 30$ ps. Muons, electrons, neutrinos and photons associated with $W$ and $Z$ decays are excluded. The particle-level jets are reconstructed with the anti-$k_t$ algorithm [12] with a radius parameter $R = 0.4$ and are required to have a $p_T$ above 25 GeV and an absolute value of pseudorapidity below 4.5.

4. Simulated event samples

Monte Carlo (MC) simulation is used to model signal and background processes. All generated MC events are passed through the ATLAS detector simulation [13], based on GEANT4 [14], and processed using the same reconstruction software used for the data. The event samples include the simulation of additional proton-proton interactions (pile-up) generated with Pythia 8.186 [15] using the MSTW2008LO PDF [16] and the A2 [17] set of tuned parameters.

Scale factors are applied to simulated events to correct for the small differences between data and MC simulation in the trigger, reconstruction, identification, isolation and impact parameter efficiencies of electrons and muons [18–20]. Furthermore, the electron energy and muon momentum in simulated events are smeared to account for small differences in resolution between data and MC [20,21].

A sample of simulated $W^\pm Z$ events is used to correct the signal yield for detector effects, to extrapolate from the fiducial to the total phase space, and to compare the measurements to the theoretical predictions. The production of $W^\pm Z$ pairs and the subsequent leptonic decays of the vector bosons are generated at NLO in QCD using the POWHEG-Box v2 [22–25] generator, interfaced to the Pythia 8.210 parton shower model using the AZNLO [26] set of tuned parameters. The CT10 [27] PDF set is used for the hard-scattering process, while the CTEQ6L1 [28] PDF set is used for the parton shower. The jet multiplicity measurement is also compared to the theoretical NLO prediction from the Sherpa 2.1.1 generator [29], calculated using the CT10 PDF set in conjunction with a dedicated set of tuned parameters for the parton shower developed by the Sherpa authors [30].

The background sources in this analysis include processes with two or more electroweak gauge bosons, namely $ZZ$, $WW$ and $VVV$ ($V = W, Z$); processes with top quarks, such as $t\bar{t}$ and $t\bar{t}V$, single top and $t\bar{t}Z$; or processes with gauge bosons associated with jets or photons ($Z + j$ and $Z\gamma$). MC simulation is used to estimate the contribution from background processes with three or more leptons. Background processes with at least one misidentified lepton are evaluated using data-driven techniques and simulated events are used to assess the systematic uncertainties in these backgrounds.

The $q\bar{q} \rightarrow Z\ell\nu$, $t\bar{t}$, and single-top processes are generated at NLO using the POWHEG-Box v2 program. The CT10 PDF set is used for the matrix-element calculations. For the $ZZ$ process the parton shower is modelled with Pythia 8.186, using the
The production of events in the final state $Z \tau \tau$ requires significant jet and/or lepton activity, but the presence of the $Z$ boson allows for a clean identification of the decay products. Events are selected using triggers [39] that require at least one electron or muon with $p_T > 24$ GeV or 20 GeV, respectively, that satisfies a loose isolation requirement. Possible inefficiencies for leptons with large transverse momenta are reduced by including additional electron and muon triggers that do not include any isolation requirements with transverse momentum thresholds of $p_T = 60$ GeV and 50 GeV, respectively. Finally, a single-electron trigger requiring $p_T > 120$ GeV with less restrictive electron identification criteria is used to increase the selection efficiency for high-$p_T$ electrons.

Events are required to have a primary vertex reconstructed from at least two charged particle tracks and compatible with the luminous region. If several such vertices are present in the event, the one with the highest sum of the $p_T^2$ of the associated tracks is selected as the primary vertex of the $W^\pm Z$ production.

All final states with three charged leptons (electrons or muons $\ell$) and neutrinos from $W^\pm Z$ leptonic decays are considered. In the following, the different final states are referred to as $\mu^+\mu^-\mu^\pm$, $e^+e^-\mu^\pm$, $\mu^+\mu^-e^\mp$ and $e^+e^-e^\mp$.

Muon candidates are identified by tracks reconstructed in the muon spectrometer and matched to tracks reconstructed in the inner detector. Muons are required to pass a “medium” identification selection, which is based on requirements on the number of hits in the ID and the MS [20]. The efficiency of this selection averaged over $p_T$ and $\eta$ is larger than 98%. The muon momentum is calculated by combining the MS measurement, corrected for the energy deposited in the calorimeters, and the ID measurement. The $p_T$ of the muon must be greater than 15 GeV and its pseudorapidity must satisfy $|\eta| < 2.5$.

Electron candidates are reconstructed from energy clusters in the electromagnetic calorimeter matched to inner detector tracks. Electrons are identified using a discriminant that is the value of a likelihood function constructed with information from the shape of the electromagnetic showers in the calorimeter, track properties and track-to-cluster matching quantities of the candidate [18].

Electrons must satisfy a “medium” likelihood requirement, which provides an overall identification efficiency of 90%. The electron momentum is computed from the cluster energy and the direction of the track. The $p_T$ of the electron must be greater than 15 GeV and the pseudorapidity of the cluster must be in the range $|\eta| < 1.37$ or $1.52 < |\eta| < 2.47$.

Electron and muon candidates are required to originate from the primary vertex. Thus, the significance of the track’s transverse impact parameter calculated with respect to the beam line, $|d_0|_{\text{avg}}$, must be smaller than three for muons and less than five for electrons, and the longitudinal impact parameter, $z_0$ (the difference between the value of $z$ of the point on the track at which $d_0$ is defined and the longitudinal position of the primary vertex), is required to satisfy $|z_0 \cdot \sin(\theta)| < 0.5$ mm.

Electrons and muons are required to be isolated from other particles. The isolation requirement is based on both calorimeter and track information and is tuned for an efficiency of at least 95% for $p_T > 25$ GeV and at least 99% for $p_T > 60$ GeV [20].

Jets are reconstructed from clusters of energy deposition in the calorimeter [40] using the anti-$k_t$ algorithm [12] with a radius parameter $R = 0.4$. Events with jets arising from detector noise or other noncollision sources are discarded [41]. All jets must have $p_T > 25$ GeV and be reconstructed in the pseudorapidity range $|\eta| < 4.5$. A multivariate combination of track-based variables is used to suppress jets originating from pile-up in the ID acceptance [42]. The energy of jets is calibrated and corrected for detector effects using a combination of simulated events and in situ methods in 13 TeV data, similar to the procedure described in Ref. [43].

The transverse momentum of the neutrino is estimated from the missing transverse momentum in the event, $E_T^{\text{miss}}$, calculated as the negative vector sum of the transverse momentum of all identified hard physics objects (electrons, muons, jets), as well as an additional soft term. A track-based measurement of the soft term [44], which accounts for low-$p_T$ tracks not assigned to a hard object, is used in the analysis.

Events are required to contain exactly three lepton candidates satisfying the selection criteria described above. To ensure that the trigger efficiency is well determined, at least one of the candidate leptons is required to have $p_T > 25$ GeV and to be geometrically matched to a lepton that was selected by the trigger.

To suppress background processes with at least four prompt leptons, events with a fourth lepton candidate satisfying looser selection criteria are rejected. For this looser selection, the $p_T$ of the leptons is lowered to $p_T > 7$ GeV and “loose” identification requirements are used for both the electrons and muons. The isolation requirement uses ID track information only and is less stringent.

Candidate events are required to have at least one pair of leptons of the same flavour and of opposite charge, with an invariant mass that is consistent with the nominal $Z$ boson mass [11] to within 10 GeV. This pair is considered to be the $Z$ boson candidate. If more than one pair can be formed, the pair whose invariant mass is closest to the nominal $Z$ boson mass is taken as the $Z$ boson candidate.

The remaining third lepton is assigned to the $W$ boson decay. The transverse mass of the $W$ candidate, computed using $E_T^{\text{miss}}$ and the $p_T$ of the associated lepton, is required to be greater than 30 GeV.

Backgrounds originating from misidentified leptons are suppressed by requiring the lepton associated with the $W$ boson to satisfy more stringent selection criteria. Thus, the transverse momentum of these leptons is required to be greater than 20 GeV. Furthermore, electrons associated with the $W$ boson decay are required to pass the “tight” likelihood identification requirement [18], which has an overall efficiency of 85%. Finally, these electrons must also pass a tighter isolation requirement, tuned for an efficiency of at least 90% (99%) for $p_T > 25$ (60) GeV.

6. Background estimation

The background sources are classified into two groups: events where at least one of the candidate leptons is not a prompt lepton ( reducible background) and events where all candidates are prompt leptons or are produced in the decay of a $\tau$ (irreducible background). Candidates that are not prompt leptons are called also “misidentified” or “fake” leptons.

The reducible background, which represents about half of the total backgrounds, originates from $Z + j$, $Z\gamma$, $t\bar{t}$, $Wt$ and $WW$
production processes, with $Z + j$ and $Z\gamma$ being the dominant component (83%). The reducible backgrounds are estimated using data-driven techniques. The background from events with two or three fake leptons, e.g., from $W + jj$ and multijet processes, is negligible.

Backgrounds from $t\bar{t}$, $Wt$ and $WW + j$ events (called “top-like” in the following) are estimated by exploiting the different-flavour decay channels of these processes. These events are categorised based on whether the misidentified lepton is an electron or muon. The former are estimated in a control region containing $e^+e^-\mu^+\mu^-$ events and the latter in a $\mu^+\mu^-\mu^+\mu^-$ control region. Events in the control regions satisfy the selection criteria described in Section 5, except that a different-flavour, opposite-charge lepton pair is associated with the $Z$ boson, and the $m_{T}$ requirement is removed to increase the number of events. These requirements suppress the contamination of events with a leptonically decaying $Z'\gamma$. The dominant contribution is due to top-like processes (75%). The MC predictions for other processes are subtracted from the observed yield. The ratios of observed to expected top-like events in the control regions are $0.5 \pm 0.3$ for misidentified electrons and $1.4 \pm 0.5$ for misidentified muons, where the uncertainties are due to the statistical uncertainties of the data and MC events in the control regions. These ratios are applied to the estimated contributions from the simulated top-like backgrounds in the final $W^{\pm}Z$ selection.

The kinematic shapes of the top-like background are taken from MC simulation for the purposes of control distributions and the exclusive jet multiplicity differential cross-section calculation. The shape of the jet multiplicity distribution in the top-like control regions is well modelled by the MC simulation.

Backgrounds from $Z + j$ and $Z\gamma$ processes are estimated by defining a three-lepton $Z$ control sample in data, where two of the leptons, referred to as tight (T), meet all identification and isolation criteria described in Section 5, and the remaining lepton, referred to as loose (L), fails these requirements and instead satisfies less restrictive ones. Events in the $Z$ control sample must satisfy all other $W^{\pm}Z$ selection criteria. The $Z$ control sample is split into three categories of events, labelled as $N_{\text{LTT}}, N_{\text{LLT}}$ and $N_{\text{TTL}}$, where the first index refers to the $W$ lepton, and the second and third indexes refer to the higher- and lower-$p_T$ leptons from the $Z$ boson decay. The observed number of events in each of these categories is 1535, 61 and 204, respectively. The contribution from $Z + j$ and $Z\gamma$ events is greater than 75%. Processes with at least three prompt leptons are subtracted using the MC prediction. This includes the subtraction of $W^{\pm}Z$ events, for which the MC prediction is increased by 15% to agree with previous measurements [4]. The subtraction of top-like processes (18%) uses a procedure with a control region containing one loose lepton, analogous to the procedure described above.

The $Z + j$ and $Z\gamma$ background in the final $W^{\pm}Z$ selection is obtained by scaling the observed number of events in the $Z$ control sample by an extrapolation factor called the “fake factor”. The fake factor is measured in a data sample with two tight leptons associated with the $Z$ boson and one additional lepton that can be loose or tight. To enrich the sample in $Z + j$ and $Z\gamma$ events, the $m_{T}$ requirement is reversed and the missing transverse momentum is required to be less than 40 GeV. The fake factor is calculated as the ratio of the number of events with a tight third lepton to the number of events with a loose third lepton. The dominant contribution (>97%) to the denominator of the fake-factor ratio originates from $Z + j$ and $Z\gamma$ events. Simulation shows that the relative fractions of these two processes are similar in this region and the $Z$ control sample where the fake factor is applied, justifying the use of a single fake factor to describe both backgrounds. Processes with at least three prompt leptons contaminate the events in the numerator of the ratio, particularly at high lepton $p_T$, and are subtracted as described for the $Z$ control sample. The fake factor is computed in bins of $p_T$ of the lepton not associated with the $Z$ boson, separately for muons and electrons, and considering the different selection criteria used for leptons in the analysis. MC simulation is used to verify that the fake factors do not depend on the jet multiplicity of the event. The fake-factor values range between 0.02 and 0.1.

In brief, the $Z + j$ and $Z\gamma$ estimate in each lepton $p_T$ bin is obtained by extrapolating from events in the $Z$ control sample using the following formula:

$$N_{Z+j,Z\gamma} = (N_{\text{LTT}} - N_{\text{LTT}}^{\text{prompt}} - N_{\text{LTT}}^{\text{top}}) F_W$$

$$+ (N_{\text{LLT}} - N_{\text{LLT}}^{\text{prompt}} - N_{\text{LLT}}^{\text{top}}) F_Z$$

$$+ (N_{\text{TTL}} - N_{\text{TTL}}^{\text{prompt}} - N_{\text{TTL}}^{\text{top}}) F_{Z},$$

(1)

where $F_W$ and $F_Z$ denote the fake factors for $W$ and $Z$ leptons, $N_{\text{LTT}}^{\text{prompt}}, N_{\text{LLT}}^{\text{prompt}}$ and $N_{\text{TTL}}^{\text{prompt}}$ denote the MC prediction of processes with at least three prompt leptons, and $N_{\text{LTT}}^{\text{top}}, N_{\text{LLT}}^{\text{top}}$ and $N_{\text{TTL}}^{\text{top}}$ denote the estimate of top-like events. Both the normalisation and the kinematic shapes of the $Z + j$ and $Z\gamma$ background are estimated from the data using this methodology. The estimate of the $Z + j$ and $Z\gamma$ background is validated in a subset of the signal region containing events with $30 < m_{T} < 50$ GeV and $E_{T}^{miss} < 40$ GeV, which is enriched in background processes.

The reducible background was also assessed with an alternative procedure, the matrix method, used in the previous measurement of $W^{\pm}Z$ production at $\sqrt{s} = 8$ TeV from the ATLAS Collaboration [4]. The results agree with the estimates described above within 5%.

Irreducible background events originate from $ZZ$, $t\bar{t} + V$, $VVV$ (where $V = Z$ or $W$), $t\bar{t}Z$ and $W^{\pm}Z$ events in which at least one of the bosons decays into leptons via an intermediate $\tau$ decay. The amount of irreducible background is estimated using MC simulations. The estimate of the contribution from $W^{\pm}Z$ events decaying via $\tau$-leptons is addressed in Section 8.

About 70% of the irreducible background is due to $ZZ$ production. Events from $ZZ$ production survive the $W^{\pm}Z$ event selection either because one lepton falls outside the fiducial volume or because it falls in the fiducial acceptance of the detector but is not identified. The number of $q\bar{q} \rightarrow ZZ$ events predicted by POWHEG is scaled by 1.08 to account for NNLO QCD and NLO EW corrections [45-47]. The number of $gg \rightarrow ZZ$ events predicted by the SHERPA MC event sample is scaled by a factor of 1.52 to account for NLO QCD corrections [48]. These estimates are validated by comparing the MC predictions with the observed event yield, and the distributions of several kinematic variables, in a four-lepton data sample enriched in $ZZ$ events. The number of observed events in this validation region is 106, with 89% purity for the $ZZ$ process. Overall agreement between the data and the predictions is within one standard deviation of the experimental uncertainty. The shapes of the distributions of the main kinematic variables are also found to be well described by the MC predictions.

7. Detector-level results

Table 1 summarises the predicted and observed numbers of events together with the estimated background contributions. The total uncertainties affecting the predicted yields include statistical uncertainties, the theoretical uncertainties in the cross sections as further discussed in Section 10, experimental uncertainties discussed in Section 9 and uncertainty in the integrated luminosity for backgrounds estimated using MC predictions. Fig. 1 shows the
Table 1
Observed and expected numbers of events after the $W^\pm Z$ inclusive selection described in Section 5 in each of the considered channels and for the sum of all channels. The expected number of $W^\pm Z$ events from Powheg+Pythia and the estimated number of background events from other processes are detailed. The total uncertainties quoted include the statistical uncertainties, the theoretical uncertainties in the cross sections, the experimental uncertainties and the uncertainty in the integrated luminosity.

Fig. 1. The distributions for the sum of all channels of the kinematic variables (a) the transverse momentum of the reconstructed $Z$ boson $p_T^Z$, (b) the reconstructed $Z$ boson mass $m_Z$, (c) the transverse mass of the reconstructed $W$ boson $m_T^W$ and (d) the transverse mass variable $m_T^{\ell \ell}$ for the $W^\pm Z$ system. The points correspond to the data, and the histograms correspond to the predictions of the different SM processes. All Monte Carlo predictions are scaled to the integrated luminosity of the data using the predicted MC cross sections of each sample. The sum of the background processes with misidentified leptons is labelled "Misid. leptons". The Powheg+Pythia MC prediction is used for the $W^\pm Z$ signal contribution. It is scaled by a global factor of 1.18 to match the measured inclusive $W^\pm Z$ cross section. The open red histogram shows the total prediction; the shaded violet band is the total uncertainty of this prediction. The last bin contains the overflow. The lower panels in each figure show the ratio of the data points to the open red histogram with their respective uncertainties. (For interpretation of the references to colour in this figure legend, the reader is referred to the web version of this article.)
measured distributions of the transverse momentum and the invariant mass of the Z candidate, the transverse mass of the W candidate, and for the WZ system a variable $m_{WZ}$ [4] similar to the transverse mass. The Powheg+Pythia MC prediction is used for the $W^\pm Z$ signal contribution. In Fig. 1 this contribution is scaled by a global factor of 1.18 to match the measured inclusive $W^\pm Z$ cross section in Section 10. This scaling is only used for an illustrative purpose in this figure and does not affect the measurements. Fig. 1 indicates that the MC predictions provide a fair description of the shapes of the data distributions.

### 8. Corrections for detector effects and acceptance

For a given channel $W^\pm Z \rightarrow \ell^+\ell^-\ell^+\ell^-$, where $\ell$ and $\ell'$ are either an electron or a muon, the integrated fiducial cross section, which includes the leptonic branching fractions of the W and Z, is calculated as

$$
\sigma_{W^\pm Z \rightarrow \ell^+\ell^-\ell^+\ell^-}^{\text{fid}} = \frac{N_{\text{data}} - N_{\text{bkg}}}{L \cdot C_{WZ}} \times \left(1 - \frac{N_{\ell}}{N_{\text{all}}}\right),
$$

(2)

where $N_{\text{data}}$ is the number of observed events, $N_{\text{bkg}}$ is the estimated number of background events, $L$ is the integrated luminosity and $C_{WZ}$, obtained from simulation, is the ratio of the number of selected signal events at detector level to the number of events at particle level in the fiducial phase space defined after QED FSR. This factor corrects for detector efficiency and resolution effects and for QED FSR effects. The term in parentheses represents the correction applied to the measurement to account for the $\tau$-lepton contribution to the analysis phase space. This contribution is estimated using the simulation, from the ratio of $N_{\ell}$, the number of selected events in which at least one of the bosons decays into a $\tau$ lepton, and $N_{\text{all}}$, the number of selected WZ events with decays into any lepton.

The $C_{WZ}$ factors for the $W^\pm W^\mp$, $W^\pm Z$ and $W^\pm Z$ inclusive processes, as well as the $\tau$-lepton contribution to the analysis phase space, $N_{\ell}/N_{\text{all}}$, are computed with Powheg+Pythia for each of the four leptonic channels and are shown in Table 2.

The total cross section is calculated as

$$
\sigma_{W^\pm Z} = \frac{\sigma_{W^\pm Z \rightarrow \ell^+\ell^-\ell^+\ell^-}^{\text{fid}}}{b_{W} \cdot b_{Z} \cdot N_{WZ}},
$$

(3)

where $b_{W} = 10.86 \pm 0.09\%$ and $b_{Z} = 3.3658 \pm 0.0023\%$ are the $W$ and $Z$ leptonic branching fractions [11], respectively, and $A_{WZ}$ is the acceptance factor calculated at particle level as the ratio of the number of events in the fiducial phase space to the number of events in the total phase space as defined in Section 3.

A single acceptance factor of $A_{WZ} = 0.343 \pm 0.002$ (stat.) is obtained using the Powheg+Pythia simulation by averaging the acceptance factors computed in the $\mu ee$ and $e\mu\mu$ channels. The use of these channels avoids the ambiguity arising from the assignment at particle level of final-state leptons to the $W$ and $Z$ bosons. Cross-section differences between $\ell^+\ell^-$ and $\ell\ell\ell$ channels caused by interference effects due to the three identical leptons in the $\ell\ell\ell$ final states are shown by simulation to be below 1%.

The differential detector-level distribution of the exclusive jet multiplicity is corrected for detector resolution and for QED FSR effects using an iterative Bayesian unfolding method [49,50]. Simulated signal events from Powheg+Pythia are used to obtain a response matrix that accounts for bin-to-bin migration effects between the reconstructed and particle-level distribution.

### 9. Systematic uncertainties

The systematic uncertainties in the measured cross sections are due to experimental and theoretical uncertainties in the acceptance, uncertainties in the correction procedure for detector effects, uncertainties in the background estimation and uncertainties in the luminosity.

The theoretical systematic uncertainties in the $A_{WZ}$ and $C_{WZ}$ factors are evaluated by taking into account the uncertainties related to the choice of PDF set, to the QCD renormalisation $\mu_R$ and factorisation $\mu_F$ scales and to the parton showering simulation. The uncertainties due to the choice of PDF are computed using the CT10 eigenvectors and the envelope of the differences between the CT10 and CT14 [51], MMHT2014 [52] and NNPDF 3.0 [53] PDF sets, according to the PDF4LHC recommendations [54]. The QCD scale uncertainties are estimated by varying $\mu_R$ and $\mu_F$ by factors of two around the nominal scale $m_{WZ}/2$ with the constraint $0.5 \leq \mu_R/\mu_F \leq 2$, where $m_{WZ}$ is the invariant mass of the $WZ$ system. Uncertainties arising from the choice of parton shower model are obtained from Ref. [4]. None of the three sources of theoretical uncertainty have a significant effect on the $C_{WZ}$ factors. The uncertainty in the acceptance factor $A_{WZ}$ is less than 0.5% due to PDF choice, and less than 0.7% due to QCD scale choice.

The uncertainty in the unfolded jet multiplicity distribution arising from the MC modelling of the response matrix in the unfolding procedure is estimated by reweighting the simulated events at particle level to match the unfolded results obtained as described in Section 8. An alternative response matrix is defined using these reweighted MC events and is used to unfold the Powheg+Pythia reconstructed events. The systematic uncertainty is estimated by comparing this unfolded distribution to the original particle-level Powheg+Pythia prediction. The size of this uncertainty is at most 15%.

The experimental systematic uncertainty in the $C_{WZ}$ factors and in the unfolding procedure includes uncertainties in the scale and resolution of the electron energy, muon momentum, jet energy and $E_{\text{miss}}$, as well as uncertainties in the scale factors applied to the simulation in order to reproduce the trigger, reconstruction, identification and isolation efficiencies measured in data. The uncertainties in the jet energy scale are obtained from $\sqrt{s} = 13$ TeV simulations and in situ measurements, similar to the ones described in Ref. [43]. The uncertainty in the jet energy resolution is derived by extrapolating measurements in Run-1 data to $\sqrt{s} = 13$ TeV. The uncertainty in the $E_{\text{miss}}$ is estimated by propagating the uncertainties in the transverse momenta of hard physics objects and by applying momentum scale and resolution uncertainties to the track-based soft term. The uncertainty associated with pile-up modelling is of the order of 1% and can reach up to 2.9% in the 0-jet bin of the unfolded jet multiplicity distribution. For the measurements of the $W$ charge-dependent cross sections, an uncertainty arising from the charge misidentification of leptons is also considered. It affects only electrons and leads to an uncertainty of less than 0.05% in the ratio of $W^+Z$ to $W^-Z$ integrated cross sections determined by combining the four decay channels.

The dominant contribution among the experimental systematic uncertainties in the $ee$ and $\mu e$ channels is due to the uncertainty in the electron identification efficiency, contributing at most 1.4% uncertainty to the integrated cross section, while in the $e\mu\mu$
and $\mu\mu\mu$ channels it originates from the muon reconstruction efficiency and is at most 1.1%. The systematic uncertainties in the measured cross sections are determined by repeating the analysis after applying appropriate variations for each source of systematic uncertainty to the simulated samples. The dominant uncertainty in the reducible $t\bar{t}$, $Wt$ and $WW + j$ background arises from the number of data and MC events in the control regions used to estimate the top-like processes and amounts to 32% of the estimated yield. An uncertainty of 2% is assigned due to the extrapolation from the control regions to the $W^\pm Z$ signal region.

The statistical precision of 3% in the reducible $Z + j$ and $Z\gamma$ background estimate is determined by the size of the $N_{LT}$, $N_{HT}$ and $N_{TT}$ categories in the $Z$ control sample. Uncertainties due to the size of the sample used to derive the fake factor amount to 21% of the estimated $Z + j$ and $Z\gamma$ yield. An uncertainty of 15% is assigned to the contributions from processes with at least three prompt leptons, which are subtracted from the sample used to derive the fake factor. This has an 18% impact on the $Z + j$ and $Z\gamma$ estimate. The uncertainty due to the subtraction of $t\bar{t}$, $Wt$ and $WW$ processes is smaller than 2%. To account for differences between the region in which the fake factor is calculated and the $Z$ control sample where it is applied, including the different relative contributions from $Z + j$ and $Z\gamma$ processes in each region, the fake factor is calculated using MC events in both regions, and the full difference between the two is taken as a systematic uncertainty, representing 26% of the estimated $Z + j$ and $Z\gamma$ yield. Overall, the $Z + j$ and $Z\gamma$ background is estimated with a precision of 38%.

A theoretical uncertainty in the $ZZ$ cross section of 8% [45–48] is assigned as a global uncertainty in the amount of $ZZ$ background predicted by the MC simulation. An additional uncertainty of 3% to 6% is assigned due to the correction applied to $ZZ$ MC events with unidentified leptons.

The uncertainty due to other irreducible background sources is evaluated by propagating the uncertainty in their MC cross sections. These are 13% (12%) for $tW \ (t\bar{t}Z)$ [37], 20% for $VVV$ [55] and 15% for $tZ$ [4].

An uncertainty in the integrated luminosity of 2.1% is applied to the signal normalisation as well as to all background contributions that are estimated purely using MC simulations. The uncertainty is derived following a methodology similar to that detailed in Refs. [56,57], from a calibration of the luminosity scale using $x$–$y$ beam-separation scans performed in August 2015. It has an effect of 2.4% on the measured cross sections.

The total systematic uncertainty in the $W^\pm Z$ fiducial cross section, excluding the luminosity uncertainty, varies between 4% and 10% for the four different measurement channels, and is dominated by the uncertainty in the reducible background estimate. The statistical uncertainty in the fiducial cross-section measurement is slightly larger than the systematic uncertainty. Table 3 shows the statistical uncertainty and main sources of systematic uncertainty in the $W^\pm Z$ fiducial cross section for each of the four channels and their combination.

### 10. Cross-section measurements

The measured fiducial cross sections in the four channels are combined using a $\chi^2$ minimisation method that accounts for correlations between the sources of systematic uncertainty affecting each channel [58–60]. The combination of the $W^\pm Z$ cross sections in the fiducial phase space yields a total $\chi^2$ per degree of freedom ($n_{\text{dof}}$) of $\chi^2/n_{\text{dof}} = 6.9/3$. The combinations of the $W^+ Z$ and the $W^- Z$ cross sections separately yield $\chi^2/n_{\text{dof}} = 5.3/3$ and 2.0/3, respectively.

Combining the four channels to obtain a weighted mean value, the cross section of $W^\pm Z$ production and decay to a single leptonic channel with muons or electrons in the detector fiducial region is

$$\sigma_{W^\pm Z \rightarrow \ell^+\ell^-\ell} = 1.80 \pm 0.10 \ (\text{stat.}) \pm 0.08 \ (\text{sys.}) \pm 0.06 \ (\text{lumi.}) \ (5)$$

All uncertainties are treated as uncorrelated between the measurements at the two beam energies. The measured ratio is in good agreement with the Standard Model prediction of $1.78 \pm 0.03$ from POWHEG+PYTHIA.

The ratio of $W^+ Z$ to $W^- Z$ production cross sections is

$$\frac{\sigma_{W^+ Z \rightarrow \ell^+\ell^-\ell}}{\sigma_{W^- Z \rightarrow \ell^+\ell^-\ell}} = 1.39 \pm 0.14 \ (\text{stat.}) \pm 0.03 \ (\text{sys.}) \ (6)$$

Most of the systematic uncertainties, especially the luminosity uncertainty, cancel in the ratio, and the measurement compared to the SM prediction. This is also shown in Table 3.

Fig. 2. Ratio of the measured $W^\pm Z$ integrated cross sections in the fiducial phase space to the NLO SM prediction from Powheg+Pythia in each of the four channels and for their combination. The inner and outer error bars on the data points represent the statistical and total uncertainties, respectively. The NLO SM prediction from Powheg+Pythia using the CT10 PDF set is represented by the red line; the shaded violet band is the total uncertainty in this prediction. (For interpretation of the reference to colour in this figure legend, the reader is referred to the web version of this article.)

Table 4
Fiducial integrated cross section in fb, for $W^\pm Z$, $W^+ Z$ and $W^- Z$ production, measured in each of the $e\mu$, $ee\mu\mu$, and $\mu\mu\mu\mu$ channels and all four channels combined. The statistical ($\delta_{\text{stat.}}$), total systematic ($\delta_{\text{sys.}}$), luminosity ($\delta_{\text{lumi.}}$) and total ($\delta_{\text{tot}}$) uncertainties are given in percent.

</table>

is dominated by the statistical uncertainty. The measured cross-section ratios, for each channel and for their combination, are compared in Fig. 3 to the SM prediction of $1.47^{+0.02}_{-0.06}$ which is calculated with Powheg+Pythia and the CT10 PDF set.

The combined fiducial cross section is extrapolated to the total phase space. The result is

$$\sigma_{W^\pm Z}^{\text{tot}} = 50.6 \pm 2.6 (\text{stat.}) \pm 2.0 (\text{sys.}) \pm 0.9 (\text{th.}) \pm 1.2 (\text{lumi.}) \, \text{pb},$$

where the theoretical uncertainty accounts for the uncertainties in the $A_{FB}$ factor due to the choice of PDF set, QCD scales and parton shower model. The NLO SM prediction calculated with Powheg+Pythia is 42.4 ± 0.8 (PDF) ± 1.6 (scale) pb. A recent calculation [7] of the $W^\pm Z$ production cross section at NNLO in QCD with MATRIX, obtained using the NNPDF3.0 PDF set and with $\mu_R$ and $\mu_F$ scales fixed to $(m_W + m_Z)/2$, yields $48.2^{+1.1}_{-1.0}$ (scale) pb, which is in better agreement with the measurement. As this prediction does not include effects of QED final-state radiation, a correction factor of 0.972 as estimated from Powheg+Pythia is applied.

Finally, the exclusive jet multiplicity cross section is presented in Fig. 4 and compared to the predictions from Powheg+Pythia and SHERPA. The shape of the measured cross section as a function of jet multiplicity is described well by SHERPA, but it is reproduced poorly by Powheg+Pythia. The matrix-element calculation in the SHERPA prediction includes up to three jets at LO, while in the Powheg+Pythia prediction only the leading jet is included, and higher jet multiplicities are described by the parton shower models.

11. Conclusion

Measurements of $W^\pm Z$ production in $\sqrt{s} = 13$ TeV $pp$ collisions at the LHC are presented. The data were collected with the ATLAS detector in 2015 and correspond to an integrated luminosity of 3.2 fb$^{-1}$. The measurements use leptonic decay modes of the gauge bosons to electrons or muons and are performed in a fiducial phase space closely matching the detector acceptance. The measured inclusive cross section in the fiducial region for one leptonic decay channel is $\sigma_{W^\pm Z}^{\text{fid.}} = 63.2 \pm 3.2 (\text{stat.}) \pm 2.6 (\text{sys.}) \pm 1.5 (\text{lumi.}) \, \text{fb}$. The NLO Standard Model prediction from Powheg+Pythia is $53.4^{+3.6}_{-3.8}$ fb. The measured cross section is higher than the SM NLO prediction; a similar excess was found in the cross-section measurements performed at lower centre-of-mass energies by the ATLAS Collaboration.

The ratio of the measured cross sections at the two centre-of-mass energies yields $\sigma_{W^\pm Z}^{\text{fid.13 TeV}} / \sigma_{W^\pm Z}^{\text{fid.8 TeV}} = 1.80 \pm 0.10 (\text{stat.}) \pm 0.08 (\text{sys.}) \pm 0.06 (\text{lumi.})$, in good agreement with the SM NLO prediction of 1.78 ± 0.03 from Powheg+Pythia. The $W^+$ and
$W^+Z$ production cross sections are measured separately in the fiducial phase space and are reported; their ratio is $\sigma_{\text{fid}}^{W^+Z\rightarrow1\ell\nu\ell}/\sigma_{\text{fid}}^{W^+Z\rightarrow1\ell\nu\ell} = 1.39 \pm 0.14(\text{stat}) \pm 0.03(\text{sys})$. This result is in agreement with the SM NLO expectation from POWHEG+PYTHIA of $1.47\pm0.08$. The measured cross section extrapolated to the total phase space is $50.6\pm2.6(\text{stat}) \pm 2.0(\text{sys}) \pm 0.9(\text{th}) \pm 1.2(\text{lumi})$ pb, in very good agreement with the SM NNLO prediction from MATRIX of $48.2^{+4.1}_{-3.0}(\text{scale})$ pb.

Finally, the $W^+Z$ production cross section is measured as a function of the exclusive jet multiplicity and compared to the SM predictions of POWHEG+PYTHIA and SHERPA. The SHERPA prediction is found to provide a better description of the data, at low and high jet multiplicities.

**Acknowledgements**

We thank CERN for the very successful operation of the LHC, as well as the support staff from our institutions without whom ATLAS could not be operated efficiently.

We acknowledge the support of ANPCyT, Argentina; YerPhI, Armenia; ARC, Australia; BMWFW and FWF, Austria; ANAS, Azerbaijan; SSTC, Belarus; CNPq and FAPESP, Brazil; NSERC, NRC and CFI, Canada; CERN; CONICYT, Chile; CAS, MOST and NSFC, China; COLCIENCIAS, Colombia; MSMT CR, MPO CR and VSC CR, Czech Republic; DNRF and DNSRC, Denmark; IN2P3-CNRS, CEA-DSM/IRFU, France; GNSF, Georgia; BMBF, HGF, and MPG, Germany; GSRT, Greece; RCUK, Hong Kong SAR, China; ISF, I-CORE and Benoziyo Center, Israel; INFN, Italy; MEKT and JSPS, Japan; CNRST, Morocco; FOM and NWO, Netherlands; RCN, Norway; MNISW and NCN, Poland; FCT, Portugal; MNE/IFA, Romania; MES of Russia and NRC KI, Russian Federation; JINR; MESTD, Serbia; MSSR, Slovakia; ARRS and MIZŠ, Slovenia; DST/NRF, South Africa; MINISEC, Spain; SRC and Knut and Alice Wallenberg Foundation, Sweden; SERI, SNSF and Cantons of Bern and Geneva, Switzerland; MOST, Taiwan; TAEK, Turkey; STFC, United Kingdom; DOE and NSF, United States of America. 132 (a) INFN Sezione di Roma; (b) Dipartimento di Fisica, Sapienza Università di Roma, Roma, Italy
133 (e) INFN Sezione di Roma Tor Vergata; (f) Dipartimento di Fisica, Università di Roma Tor Vergata, Roma, Italy
134 (g) INFN Sezione di Roma Tre; (h) Dipartimento di Matematica e Fisica, Università Roma Tre, Roma, Italy
135 (i) Faculté des Sciences Ain Chock, Université de l'Apuricque et des Hautes Énergies – Université Hassan II, Casablanca; (j) Centre National de l'Énergie des Sciences Techniques Nucléaires, Rabat; (k) Faculté des Sciences Semlalia, Université Cadi Ayyad, LHEA-Maroc; (l) Faculté des Sciences, Université Mohamed Premier and LPTPM, Oujda; (m) Faculté des sciences, Université Mohammed V, Rabat, Morocco
136 (n) DSM/IRFU (Institut de Recherches sur les Lois Fondamentales de l'Univers), CEA Saclay (Commissariat à l'Energie Atomique et aux Energies Alternatives), GIF-sur-Yvette, France
137 Santa Cruz Institute for Particle Physics, University of California Santa Cruz, Santa Cruz CA, United States
138 Department of Physics, University of Washington, Seattle WA, United States
139 Department of Physics and Astronomy, University of Sheffield, Sheffield, United Kingdom
140 Department of Physics, Shinshu University, Nagano, Japan
141 Fachbereich Physik, Universität Siegen, Siegen, Germany
142 Department of Physics, Simon Fraser University, Burnaby BC, Canada
143 SLAC National Accelerator Laboratory, Stanford CA, United States
144 (a) Faculty of Mathematics, Physics & Informatics, Comenius University, Bratislava; (b) Department of Subnuclear Physics, Institute of Experimental Physics of the Slovak Academy of Sciences, Kosice, Slovak Republic
145 (c) Department of Physics, University of Cape Town, Cape Town; (d) Department of Physics, University of Johannesburg, Johannesburg; (e) School of Physics, University of the Witwatersrand, Johannesburg, South Africa
146 (f) Department of Physics, Stockholm University; (g) The Oskar Klein Centre, Stockholm, Sweden
147 Physics Department, Royal Institute of Technology, Stockholm, Sweden
148 Departments of Physics & Astronomy and Chemistry, Stony Brook University, Stony Brook NY, United States
149 Department of Physics and Astronomy, University of Sussex, Brighton, United Kingdom
150 School of Physics, University of Sydney, Sydney, Australia
151 Institute of Physics, Academia Sinica, Taipei, Taiwan
152 Department of Physics, Technion: Israel Institute of Technology, Haifa, Israel
153 Raymond and Beverly Sackler School of Physics and Astronomy, Tel Aviv University, Tel Aviv, Israel
154 Department of Physics, Aristotle University of Thessaloniki, Thessaloniki, Greece
155 International Center for Elementary Particle Physics and Department of Physics, The University of Tokyo, Tokyo, Japan
156 Graduate School of Science and Technology, Tokyo Metropolitan University, Tokyo, Japan
157 Department of Physics, Tokyo Institute of Technology, Tokyo, Japan
158 Department of Physics, University of Toronto, Toronto ON, Canada
159 (a) TRIUMF, Vancouver BC; (b) Department of Physics and Astronomy, York University, Toronto ON, Canada
160 Faculty of Pure and Applied Sciences, and Center for Integrated Research in Fundamental Science and Engineering, University of Tsukuba, Tsukuba, Japan
161 Department of Physics and Astronomy, Tufts University, Medford MA, United States
162 Department of Physics and Astronomy, University of California Irvine, Irvine CA, United States
163 (c) INFN Gruppo Collegato di Udine, Sezione di Trieste, Udine; (d) ICTP, Trieste; (e) Dipartimento di Chimica, Fisica e Ambiente, Università di Udine, Udine, Italy
164 Department of Physics and Astronomy, University of Uppsala, Uppsala, Sweden
165 Department of Physics, University of Illinois, Urbana IL, United States
166 Instituto de Física Corpuscular (IFIC) and Departamento de Física Atómica, Molecular y Nuclear and Departamento de Ingeniería Electrónica y Instituto de Microelectrónica de Barcelona (IMB-CNM), University of Valencia and CSIC, Valencia, Spain
167 Department of Physics, University of British Columbia, Vancouver BC, Canada
168 Department of Physics and Astronomy, University of Victoria, Victoria BC, Canada
169 Department of Physics, University of Warwick, Coventry, United Kingdom
170 Waseda University, Tokyo, Japan
171 Department of Particle Physics, The Weizmann Institute of Science, Rehovot, Israel
172 Department of Physics, University of Wisconsin, Madison WI, United States
173 Fakultät für Physik und Astronomie, Julius-Maximilians-Universität, Würzburg, Germany
174 Fakultät für Mathematik und Naturwissenschaften, Fachgruppe Physik, Bergische Universität Wuppertal, Wuppertal, Germany
175 Department of Physics, Yale University, New Haven CT, United States
176 Yerevan Physics Institute, Yerevan, Armenia
177 Centre de Calcul de l’Institut National de Physique Nucleaire et de Physique des Particules (IN2P3), Villeurbanne, France

a Also at Department of Physics, King’s College London, London, United Kingdom.
b Also at Institute of Physics, Azerbaijan Academy of Sciences, Baku, Azerbaijan.
c Also at Novosibirsk State University, Novosibirsk, Russia.
d Also at TRIUMF, Vancouver BC, Canada.
e Also at Department of Physics & Astronomy, University of Louisville, Louisville, KY, United States.
f Also at Department of Physics, California State University, Fresno CA, United States.
g Also at Department of Physics, University of Freiburg, Freiburg, Switzerland.
h Also at Department of Fisica de la Universitat Autonoma de Barcelona, Barcelona, Spain.
