(Received 30 August 2016; published 23 January 2017)

In this work we study the particle conductance of a strongly interacting Fermi gas through a quantum point contact. With an atom-molecule two-channel model, we compute the contribution to particle conductance by both the fermionic atoms and the bosonic molecules using the Keldysh formalism. Focusing on the regime above the Fermi superfluid transition temperature, we find that the fermionic contribution to the conductance is reduced by interaction compared with the quantized value for the noninteracting case; while the bosonic contribution to the conductance exhibits a plateau with nonuniversal values that is larger than the quantized conductance. This feature is particularly profound at temperature close to the superfluid transition. We emphasize that the enhanced conductance arises because of the bosonic nature of closed channel molecules and the low dimensionality of the quantum point contact.

DOI: 10.1103/PhysRevA.95.013623

I. INTRODUCTION

The quantized conductance for transport through a quantum point contact (QPC) is one of the most prominent phenomena in mesoscopic physics [1,2]. The quantization in units of $2e^2/h$ is well understood in terms of the Landauer-Büttiker formalism [3,4] for noninteracting electrons, where $e$ is the electric charge and $h$ is Planck’s constant. Recently, experimental advances in cold atom systems have made it possible to engineer mesoscopic tunnel junctions between two reservoirs of degenerate quantum gases. The advantage of this novel system is that one can tune the interatomic interaction to study the interaction and correlation effects in the mesoscopic transport phenomena in a highly controllable manner. In 2015, the quantized conductance of noninteracting neutral Fermi atoms was observed by the ETH group where the conductance is found to be quantized in units of $1/h$ [5]. Subsequently, the transport properties of strongly interacting Fermi gases through QPCs were also investigated experimentally for both the superfluid state [6] and the normal state [7].

Of particular interest is the anomalous conductance discovered in the normal state of a strongly interacting Fermi gas through a QPC [7]. It is found that the height of the conductance plateau can be enhanced to a nonuniversal value, which can be several times of $1/h$, as the interaction strength increases. This anomalous conductance is qualitatively different from the conductance anomalies observed in solid state QPC, where it is usually reduced. In this paper we put forward one possible explanation for the enhanced conductance observed experimentally. We show that the presence of molecular state, or preformed pairs, in the strongly interacting Fermi gas can contribute to a larger conductance due to the Bose statistics [8], even above the superfluid transition temperature $T_c$.

In this work the bulk properties of the strongly interacting Fermi gas in two reservoirs are described by an atom-molecule coupled two-channel model, which takes explicitly into account both fermionic and bosonic degrees of freedoms [9–11]. We focus on the normal state transport through a QPC at unitarity and adopt the Nozières and Schmitt-Rink (NSR) scheme [11,12] to calculate the spectral functions of both bosonic and fermionic components in the two reservoirs. Then we employ a tunneling Hamiltonian to describe the particle transport through a QPC, and calculate the current contributions from both the bosonic and fermionic components using the Keldysh formalism [13,14]. We find that the conductance still processes quantized plateaus. The conductance of the fermionic component is reduced due to the strong interaction effect, while that by bosons is enhanced, and this enhancement becomes stronger as one approaches the critical temperature.

II. THE MODEL

In the realistic experimental setup the cigar-shaped trap is split into two reservoirs using the repulsive potential of a TEM01-like mode of a laser. A two-dimensional channel is formed between the two reservoirs initially. Then, at the center of the two-dimensional region a QPC is created by imaging a split gate structure using high-resolution lithography [5–7]. The particles will be transferred from the three-dimensional reservoirs to a two-dimensional region first, and then enters the one-dimensional QPC. To model the tunneling process, we simplify the experimental structure as shown in Fig. 1: Two three-dimensional reservoirs are connected directly by a one-dimensional QPC. The transverse trapping frequencies $\omega_{\nu,z}$ of the QPC in the $y$ and $z$ directions are much larger than the thermal energy of the system, and as a result, the tunneling channel can be regarded as one dimensional. An additional laser beam is shone on the QPC along the $y$ direction to create an attractive gate potential $V_g$ which can tune the particle density in this region.

The total Hamiltonian of the system, consisting of two reservoirs and the QPC, can be written as (setting $\hbar = 1$)

$$\hat{H} = \hat{H}_L + \hat{H}_R + \hat{H}_T,$$

where $\hat{H}_L$ ($\hat{H}_R$) describes the left (right) reservoir and is given by

$$\hat{H}_j = \int d^3r \left\{ \sum_{\sigma} \hat{\psi}_{j\sigma}^\dagger(r) \left(-\frac{\nabla^2}{2m} - \mu_j\right) \hat{\psi}_{j\sigma}(r) + \hat{\phi}_j^\dagger(r) \left(-\frac{\nabla^2}{4m} + 2\nu - 2\mu_j\right) \hat{\phi}_j(r) + g[\hat{\psi}_{j\uparrow}(r)\hat{\psi}_{j\downarrow}(r)\hat{\phi}_j(r) + H.c.] \right\}.$$
The operator \( \hat{\psi}_j(\mathbf{r}) \) describes the creation of a fermion atom with spin \( \sigma = \uparrow, \downarrow \) in the \( j \)th reservoir with \( j = L, R \). \( m \) is the mass of fermions. Similarly, \( \hat{\phi}_j(\mathbf{k}) \) creates a diatomic molecule of mass \( 2m \) in the \( j \)th reservoir. \( 2v \) is the bare detuning of the molecular state with respect to scattering continuum and \( g \) is the bare coupling constant between the atoms and the molecules. These two parameters can be related to the \( s \)-wave scattering length \( a_s \) and the effective range \( r_0 \):}

\[
\begin{align*}
\frac{2v}{g^2} &= -\frac{m}{4\pi a_s} + \int \frac{d^2k}{(2\pi)^2} \frac{1}{2\epsilon_k}, \\
\frac{1}{g^2} &= -\frac{r_0m^2}{8\pi},
\end{align*}
\]

where \( \epsilon_k = k^2/2m \).

Finally, \( \hat{H}_T \) describes the tunneling between two reservoirs through the QPC. Within the QPC, the transverse confinement leads to the transport channels with energies given by \( \epsilon_L(n_{xy},n_{xz}) = (\epsilon_0 + (n_{xy} + n_{xz})\omega_y + (n_{xy} + n_{xz})\omega_z + V_g) \). We define an effective gate potential as \( \bar{V}_g = V_g + \frac{1}{2} \omega_y + \frac{1}{2} \omega_z \) and assume \( \omega_z \gg \omega_y \), then the eigenenergy of the several lowest transport channels would be \( n_{xy}\omega_y + \bar{V}_g \), and they are nondegenerate. The potential along the transport direction \( \hat{x} \) direction in our case, see Fig. 1) can be modeled as a saddle point potential with \( V(x) = -\frac{1}{2}m\omega_y^2x^2 \) (see Fig. 1(c) of Ref. [7]), neglecting the modification of potential to the entry and exit of the QPC. In our case, \( \omega_z \ll \omega_{y,z} \), and for this particular case, it is known that transmission matrix element through the \( n \)th channel of the QPC is energy dependent, \( T^n(E) = [1 + \text{exp}(-2\pi(E - n\omega_y - \bar{V}_g)/\omega_z)]^{-1} \) [15]. We assume that only particle with momentum along the \( \hat{x} \) direction can pass through the QPC, and away from the QPC, their energies are given by \( \epsilon(k_{j,x}) = k_{j,x}^2/2m, j = L, R \). As a result, we can make the following simplification for the tunneling matrix elements when \( \omega_x \ll \omega_{y,z} \):

\[
T_F^T(k_{L,x},k_{R,x}) = T_F \prod_{j=L,R} \Theta(\epsilon(k_{j,x}) - n\omega_y - \bar{V}_g), \quad (5)
\]

\[
T_B^T(k_{L,x},k_{R,x}) = T_B \prod_{j=L,R} \Theta\left[\epsilon(k_{j,x}) - n\omega_y - \bar{V}_g\right]/2. \quad (6)
\]

The constants \( T_{F,B} \) will be related to the transparency of the QPC later. The tunneling matrix elements above indicate that only particles with energy \( \epsilon(k_{j,x}) > n\omega_y + \bar{V}_g \) can enter the \( n \)th channel of the QPC and will come out from the same channel. Namely, we assume that there is no interchannel scattering within the QPC. With this simplification, we can write the tunneling Hamiltonian in the explicit form (now written in Heisenberg representation, for more detail see Appendix A)

\[
\hat{H}_T = \frac{1}{\mathcal{A}} \sum_n \int \frac{d\omega}{2\pi} \int \frac{dk_{L,x}}{2\pi} \int \frac{dk_{R,x}}{2\pi} 
\times \left\{ T_F^T(k_{L,x},k_{R,x}) \sum_{j} \hat{\psi}_L^\dagger(\omega,k_{L,x})\hat{\psi}_R(\omega + \Delta\mu,k_{R,x}) + T_B^T(k_{L,x},k_{R,x})\hat{\phi}_L^\dagger(\omega,k_{L,x})\hat{\phi}_R(\omega + 2\Delta\mu,k_{R,x}) + \text{H.c.}\right\}. \quad (7)
\]

Here \( \mathcal{A} \) is the cross-section area in the \( yz \) plane of the QPC. \( \Delta\mu = \mu_L - \mu_R \) are the chemical potential bias, where \( \mu_{L,R} \) is the chemical potentials for fermions of the left and right reservoirs.

### III. THE CONDUCTANCE FORMALISM

In the presence of a chemical potential bias \( \Delta\mu \), the total (atomic) current is a sum of both the fermionic and bosonic parts as \( I(t) = I_F(t) + I_B(t) \), where

\[
I_F \equiv \frac{1}{2} \left\langle \frac{\partial}{\partial t}(N_{F,R} - N_{F,L}) \right\rangle, \quad (8)
\]

\[
I_B \equiv \left\langle \frac{\partial}{\partial t}(N_{B,R} - N_{B,L}) \right\rangle. \quad (9)
\]

with \( N_{F,j} = \sum_{\sigma} \hat{\psi}_j^\dagger(\mathbf{k})\hat{\psi}_j(\mathbf{k}) \) and \( N_{B,j} = \sum_{\sigma} \hat{\phi}_j^\dagger(\mathbf{k})\hat{\phi}_j(\mathbf{k}) \) are the number operators of fermions and bosons in the two reservoirs, respectively. In the above expressions the averages \( \langle \cdots \rangle \) are taken over a time-evolving many-body state, which we implement using the Keldysh formalism [6,13,14]. To second order in \( T_{F,B} \), one obtains the expressions for the currents \( I_F(t) \) in terms of spectral functions \( A_{F,B}(\mathbf{k}) \) for fermions and bosons in the reservoirs (see Appendix B)

\[
I_F(t) = 2\alpha_F \epsilon_R^F \int \frac{d\omega}{2\pi} \int \frac{dk_x}{2\pi} \int \frac{dk_y}{2\pi} \Theta(\epsilon_L - n\omega_y - \bar{V}_g) 
\times \Theta(\epsilon_R - n\omega_y - \bar{V}_g) A_F^T(\omega,\sqrt{2m\epsilon_L}) 
\times A_F^T(\omega + \Delta\mu,\sqrt{2m\epsilon_R}) \{ n_F(\omega_f) - n_F(\omega + \Delta\mu) \}, \quad (10)
\]

where \( \epsilon_R^F \) is the Fermi energy of the right reservoir. In this work we will use \( \epsilon_R^F \) and the Fermi momentum \( k_F^R \) of the right
reservoir as the energy and the momentum units. The expression for $I_B$ is similar except that $m, \alpha_F, A_F^j$, and $n_F$ are now replaced by $2m, \alpha_B, A_B^j$, and $n_B$. Furthermore, for $I_B(t)$, $\Delta \mu_F \equiv \Delta \mu$ should be replaced by $\Delta \mu_F \equiv 2\Delta \mu$. The so-called transparency is defined as $\alpha_F(B) = 16\pi^2|I_B(B)|^2 D_F(B)(\epsilon_F^B)/A^2$, where $D_F(\epsilon) = \sqrt{2m/(4\pi \sqrt{\epsilon})}$ and $D_B(\epsilon) = \sqrt{4m/(4\pi \sqrt{\epsilon})}$ are the one-dimensional density of state for fermions and bosons, respectively. In this work we assume a perfectly transparent junction and set both $\alpha_F(B) = 1$ for simplicity. The atomic conductances are then calculated by $\sigma = \sigma_F + \sigma_B$ with $\sigma_F = I_{F,B}/\Delta \mu$.

For noninteracting fermions, the spectral functions are $\delta$ functions: $A_F^j(\omega, \sqrt{2m} \epsilon_L) = \delta(\omega - \epsilon_L + \mu_L)$ and $A_B^j(\omega, \sqrt{2m} \epsilon_R) = \delta(\omega + \Delta \mu - \epsilon_R + \mu_R)$. Then the current in Eq. (10) reduces to the standard Landauer-Büttiker formula [3,4,14] as $I_F = \frac{1}{2} \int d\epsilon \Theta(\epsilon - n\omega - \hat{V}_F)[n_F(\epsilon - \mu_L - \nu F(\epsilon - \mu_L - \nu) - n_F(\epsilon - \mu_R)]$, which exhibits quantized conductance plateaus as $\hat{V}_F$ changes. For the interacting cases, the spectral functions of fermions and bosons are given by

$$A_F^j(\omega, \mu) = -\frac{1}{\pi} \text{Im} \frac{1}{\omega - \epsilon_F - \mu - i\Sigma_F^j(\omega, \mu)}, \quad (11)$$

$$A_B^j(\omega, \mu) = -\frac{1}{\pi} \text{Im} \frac{1}{\omega - \epsilon_B/2 - 2\nu_0 + 2\mu_j - i\Sigma_B^j(\omega, \mu)}. \quad (12)$$

Here $\Sigma_F^j,\Sigma_B^j(\omega, \mu)$ is the self-energies of the bosonic and fermionic components in the $j$th reservoir and will be calculated within NSR scheme in the following.

IV. THE SPECTRAL WEIGHT FUNCTIONS OF FERMIOS AND BOSONS IN NSR SCHEME

Within the NSR scheme [11,12], the number density in $j$th reservoir is given by

$$n_j = 2 \int \frac{d^4 k}{(2\pi)^3} n_F(\epsilon_F - \mu_j)$$

$$+ \int \frac{d^4 k}{(2\pi)^3} \frac{d\omega}{\pi} n_B(\omega) \frac{\partial}{\partial \mu_j} \delta_j(\omega, \mu), \quad (13)$$

where $n_{F,B}(\omega) = (\exp[\beta \omega] \pm 1)^{-1}$ is the Fermi (Bose) distribution function. The phase shift is defined by

$$\delta_j(\omega, \mu) = -\text{arg} \left[ -\frac{\omega + \mu_j + 2\nu_0 - 2\mu_j}{g^2} - \Pi_j(\omega, \mu) \right]. \quad (14)$$

where arg means taking the phase of the expression in the bracket. Here $\nu_0 = -mg^2/(8\pi a_s)$ and the polarization $\Pi_j$ is given by

$$\Pi_j = \int \frac{d^4 p}{(2\pi)^3} \left[ \frac{-n_F(\epsilon_F - \mu_j) - n_F(\epsilon_F - \mu_j)}{-\omega + \mu_j + 2\nu_0 - 2\mu_j} - \frac{1}{2\epsilon_p} \right]. \quad (15)$$

We consider transport when both reservoirs are in the normal state above the superfluid transition temperature $T_c$, which in turn is given by the Thouless criterion

$$2\nu_0 - 2\mu_j + \int d^3 k \frac{1}{(2\pi)^3} \left[ \frac{1 - 2n_F(\epsilon_k - \mu_j)}{2\epsilon_k - 2\mu_j} - \frac{1}{2\epsilon_k} \right] = 0. \quad (16)$$

The self-energies of fermions and bosons can be calculated from the Feynman diagrams in Fig. 2. The fermion loop in Fig. 2(b) is the polarization operator $\Pi_j(\omega, \mu)$ in Eq. (15):

$$\Sigma^B_j(\omega + i0^+, \mu) = -g^2 \Pi_j(\omega + i0^+, \mu)$$

$$= g^2 \int \frac{d^3 p}{(2\pi)^3} \left[ \frac{1 - n_F(\epsilon_p - \mu) - n_F(\epsilon_p - \mu)}{\omega + i0^+ - \epsilon_p - \epsilon_p - \mu_i + i0^+} + \frac{1}{2\epsilon_p} \right]. \quad (17)$$

The self-energy of fermion can be calculated by summing the diagrams in Fig. 2(a) as

$$\Sigma^F_j(\omega, \mu) = \frac{1}{\beta} \sum_{\omega_m} \int \frac{d^3 p}{(2\pi)^3} \frac{1}{-i(\omega_m - \omega_n) + \epsilon_p - \mu_j}$$

$$\times \{ -U(i\omega_m, \mu) - U(i\omega_m, \mu)\Pi(i\omega_m, \mu)U(i\omega_m, \mu)$$

$$- U(i\omega_m, \mu)U(i\omega_m, \mu)\Pi(i\omega_m, \mu)U(i\omega_m, \mu)$$

$$+ \cdots \} \quad (18)$$

where $U(i\omega_m, \mu) = g^2(-i\omega_m + p^2/4m + 2\nu_0 - 2\mu_j)^{-1}$. After the analytical continuation we obtain the fermion self-energy as

$$\Sigma^F_j(\omega + i0^+, \mu)$$

$$= \frac{1}{\beta} \sum_{\omega_m} \int \frac{d^3 p}{(2\pi)^3} \frac{1}{\chi(\omega_m, \mu) - i0^+ - i\omega_m + (p - \mu)^2/2m - \mu_j}. \quad (19)$$

where we have defined

$$\chi(\omega_m, \mu) = -1/U(i\omega_m, \mu) + \Pi(\omega_m, \mu). \quad (20)$$
The spectral function for bosons is shown in Fig. 3 for three different momenta. It is worth noting the accumulation of spectral weight at low energy when \( k \) is small. It is this low energy spectral weight that contributes an enhanced bosonic conductance through the QPC. On the other hand, the Fermi spectral function within the NSR calculation shows broad peaks. For \( k = k_F \) (black line in inset of Fig. 3), the width of the spectral function is comparable to Fermi energy, indicating that Landau quasiparticle is not well defined within NSR. In addition, the peak position occurs away from \( \omega = 0 \), consistent with pseudogap behavior.

V. THE CONDUCTANCE RESULTS

In Fig. 4 we plot the conductances contributed by both the bosons and fermions, as well as the total conductance as functions of the effective gate potential \( V_g \). The first feature to be noted is that the conductances for both bosons and fermions still exhibit plateaus. However, the height of fermion conductance plateaus is reduced to a smaller values than the noninteracting case due to strong interaction which is consistent with a non-Fermi liquid behavior at unitarity.

On the other hand, the conductance contributed by bosons is much higher. There are two effects leading to this large bosonic conductance: (i) The boson spectral weight distribution and the Bose statistics. In Fig. 3 we show that the spectral function of the bosonic molecule is sharply peaked at small momentum at low energy in the strongly interacting regime. Meanwhile, the weight of the Bose distribution function \( n_B(\omega) = (\exp[\beta \omega] - 1)^{-1} \) increases towards the small \( \omega \) limit, and this leads to a large value of boson current in Eq. (10). (ii) The low dimensional structure of the QPC. If the QPC is just a point in three dimension, the integration over the momenta is equal to an average over a three-dimensional density of state, which vanishes as the energy approaches zero, which would have canceled the enhancement discussed in (i). However, in the one-dimensional tunneling channel we are discussing here, the density of state at low energy is finite and even diverges when approaching zero, which guarantees nonvanishing contribution and the existence of the enhancement effect, consistent with conclusion reached in Ref. [8].

In Fig. 5 we show the variation of the conductances as a function of temperature \( T > T_c \). We observe that the conductance of bosons drops to zero very fast as one increases the temperature. The effect of anomalous conductance is thus most pronounced when temperature is close to \( T_c \).
VI. DISCUSSIONS

Throughout this work, the conductance through a QPC is presented for a “narrow” Feshbach resonance, where the effective range is taken as $k_F^2 r_0 = -0.1$. We find that the contribution from the bosonic molecules can give rise to an anomalous large conductance in a strongly interacting Fermi gas. For a broad resonance, our calculation shows that the closed channel molecule fraction is about $\int d\omega A(x, \omega) \approx 10^{-4}$ for typical value of $k$ for a broad resonance of $^6$Li where $k_F^2 r_0 = -0.00016$. This small fraction significantly reduces the conductance contributed by bosons. Nevertheless, this does not mean the contribution from the bosonic degree of freedom is not important for a broad Feshbach resonance, for which the bosonic degrees of freedom exist primarily as the fluctuating Cooper pairs of open channel character.

While both Ref. [18] and our work do not assume pairing in the channel but focus on the effects of pairing fluctuation in the QPC, the strong confinement renormalizes the interaction such that pairing occurs in the channel, for which the bosonic degrees of freedom exist primarily as the fluctuating Cooper pairs of open channel character.

APPENDIX A: THE TUNNELING HAMILTONIAN

To discuss the construction of the tunneling Hamiltonian, we start with the real space tunneling Hamiltonian at point $r = 0$,

$$H_T = \sum_{n, \sigma} \left[ T_F \bar{\psi}_{L_\sigma}(0) \psi_{R_\sigma}(0) + T_B \phi_{L_\sigma}(0) \phi_{R_\sigma}(0) \right] + \text{H.c.} \tag{A1}$$

In order to investigate $H_T$ in the Keldysh framework, we need to derive the time evolution of $H_T$. Due to the chemical potential difference in two reservoirs, we use the single particle Hamiltonian $H + \sum_{\mu} (\mu N_{F_\mu} + 2\mu N_{B_\mu})$ to construct the time evolution operator as

$$U(t) = e^{i[H + \sum_{\mu} (\mu N_{F_\mu} + 2\mu N_{B_\mu})]t} \tag{A2}$$

In this case, the energies in both reservoirs are measured on the absolute scale. Then the time evolution of $H_T$ is given by

$$H_T(t) = U(t) H_T U^{-1}(t) \tag{A3}$$

$$= \sum_{n, \sigma} \left[ T_F^n e^{-i\Delta \mu} \sum_{\sigma} \bar{\psi}_{L_\sigma}(t, 0) \psi_{R_\sigma}(t, 0) + T_B^n e^{-2i\Delta \mu} \phi_{L_\sigma}(t, 0) \phi_{R_\sigma}(t, 0) \right] + \text{H.c.} \tag{A4}$$

where $\psi_{j_\sigma}(t, 0) = e^{iH_0(t, 0)} \psi_{j_\sigma}(0) e^{-iH_0(t, 0)}$ and $\phi_{j_\sigma}(t, 0) = e^{iH_0(t, 0)} \phi_{j_\sigma}(0) e^{-iH_0(t, 0)}$.

APPENDIX B: THE KELDYSH FORMALISM OF THE TUNNELING HAMILTONIAN

To study the particle transport through the QPC, we follow the Keldysh formalism on a closed time contour [14]. The action of the left and right reservoir can be written as

$$S_i = \int d\tilde{x} dt \left\{ \sum_{\sigma} \bar{\psi}_{j_\sigma}(G_{F_\sigma})^{-1} \psi_{j_\sigma} + \Phi_j^\dagger(G_{B_\sigma})^{-1} \Phi_j \right. \tag{B1}$$

+ $g \left( \phi_{j_\sigma}^\dagger \bar{\psi}_{j_\sigma} \right) + \left. \phi_j^\dagger \bar{\psi}_j + H.c. \right\}$. 

013623-5
where the bosonic and fermionic coherent fields are given by
\[ \Psi_{j\sigma} = (\bar{\psi}_{j\sigma} + \phi_{j\sigma}), \]  
\[ \Phi_j = (\phi^0_j, \phi^1_j). \]

The quantum and classical fields are defined as usual in the following [14]:
\[ \phi_j^0 = \frac{1}{\sqrt{2}}(\phi_j^+ - \phi_j^-), \phi_j^1 = \frac{1}{\sqrt{2}}(\phi_j^+ + \phi_j^-). \]

The fermionic and bosonic propagators are given in Keldysh along the forward (backward) branch of the time contour [14].

The retarding (advanced) Green function of fermions is given by
\[ G_{Fj}^{R(A)} = \frac{1}{\omega - k^2/2m + \mu_j \pm i0^+} \]
and the Keldysh Green function
\[ G_{Fj}^{K} = [1 - 2n_p(\omega)](G_{Fj}^{R} - G_{Fj}^{A}). \]

The retarding (advanced) Green function of bosons in momentum space is given by
\[ G_{Bj}^{R(A)} = \frac{1}{\omega - k^2/4m - 2v + 2\mu_j \pm i0^+} \]

By Fourier transformation, the currents can be expressed as
\[ I_F(t) = \frac{1}{2}\langle \frac{\delta(N_{R}^{F} - N_{L}^{F})}{\partial t} \rangle = \frac{1}{2i\hbar}[H, N_{R}^{F} - N_{L}^{F}], \]
\[ I_B(t) = \frac{1}{2i\hbar}[H, N_{R}^{B} - N_{L}^{B}]. \]

The factor of 2 in the above definition is because two fermions are transferred when one boson passes through the QPC. For convenience, we calculate the current in the momentum space. By Byrion transformation, the currents can be expressed as
\[ I_F(\Omega) = \frac{1}{A}\sum \int d\omega dk_{L,x} dk_{R,x} \frac{2\pi}{2\pi} \int d\omega dk_{L,x} dk_{R,x} \frac{2\pi}{2\pi} \left\{ i\tilde{T}^{R}_{F}(k_{L,x}, k_{R,x}) \tilde{\psi}_{R\sigma}(\omega + \Delta \mu, k_{L,x}) \right\} + H.c., \]
\[ I_B(\Omega) = \frac{1}{A}\sum \int d\omega dk_{L,x} dk_{R,x} \frac{2\pi}{2\pi} \int d\omega dk_{L,x} dk_{R,x} \frac{2\pi}{2\pi} \left\{ i\tilde{T}^{A}_{B}(k_{L,x}, k_{R,x}) \tilde{\phi}_{L}(\omega + \Delta \mu, k_{L,x}) \right\} + H.c. \]

We introducing a time-dependent external source fields \( A(t) \) to generate the fermionic and bosonic current. The partition function of the whole system in the momentum space can be written as
\[ Z = \frac{1}{\lambda} \int D\tilde{\psi}_{\sigma}, \tilde{\phi}_{\sigma}, \phi_{j} \exp(iS). \]

where \( S = S_0 + S_i + S_T + S_s \), and \( S_0, S_i, S_T, \) and \( S_s \) correspond to the free, interaction, tunneling, and source terms, respectively. They can be expressed in the momentum space as the following:
\[ S_0 = \int \frac{d\omega}{2\pi} \sum \int d^3k (\sum_{\sigma} \psi_{j\sigma}(\omega, k)G_{Fj}(\omega, k))^{-1} \psi_{j\sigma}(\omega, k) G_{Bj}(\omega, k). \]
\[ S_i = \int \frac{d\omega_1 d\omega_2}{2\pi} \sum \int d^3k_1 d^3k_2 \left\{ \phi^0_{i}(\omega_1, k_1, k_2) \left\{ \tilde{\psi}_{j1\sigma}(\omega_1, k_1) \tilde{\psi}_{j2\sigma}(\omega_2, k_2) + \tilde{\psi}_{j2\sigma}(\omega_1, k_1) \tilde{\psi}_{j1\sigma}(\omega_2, k_2) \right\} + \phi^1_{i}(\omega_1, k_1, k_2) \left\{ \tilde{\psi}_{j1\sigma}(\omega_1, k_1) \tilde{\psi}_{j2\sigma}(\omega_2, k_2) + \tilde{\psi}_{j2\sigma}(\omega_1, k_1) \tilde{\psi}_{j1\sigma}(\omega_2, k_2) \right\} \right\}. \]
\[ S_T = J^O_{F}(0) + J^O(0)B + H.c., \]
\[ S_s = i \int \frac{d\Omega}{2\pi} \{ A^O(\Omega) [J^O_F(-\Omega) + 2J^O_R(-\Omega) + A^Q(\Omega) [J^O_F(-\Omega) + 2J^O_R(-\Omega)] + H.c. \}

\[ 013623-6 \]
In the above partition function $A^{cl} = \frac{1}{2}(A^+ + A^-)$ and $A^n = \frac{1}{2}(A^+ - A^-)$, where $A^+$ and $A^-$ are the external field along the forward and backward time direction. We have defined
\[
J^i_F(\Omega) = \frac{1}{A^2} \sum_n \int \frac{d\omega}{2\pi} d\omega_{kL} d\omega_{kR} \times T^i_F(\omega_{kL}, \omega_{kR}) \sum_{\sigma} [\bar{\psi}_{1\sigma}(\omega, k_{L,x}) \psi_{2\sigma}(\Omega + \omega + \Delta \mu, k_{R,x}) + \bar{\psi}_{2\sigma}(\omega, k_{L,x}) \psi_{1\sigma}(\Omega + \omega + \Delta \mu, k_{R,x})].
\]
\[
J^i_B(\Omega) = \frac{1}{A^2} \sum_n \int \frac{d\omega}{2\pi} d\omega_{kL} d\omega_{kR} \times T^i_B(\omega_{kL}, \omega_{kR}) \sum_{\sigma} [\bar{\psi}_{1\sigma}(\omega, k_{L,x}) \psi_{2\sigma}(\Omega + \omega + \Delta \mu, k_{R,x}) + \bar{\psi}_{2\sigma}(\omega, k_{L,x}) \psi_{1\sigma}(\Omega + \omega + \Delta \mu, k_{R,x})].
\]
\[
J^i_R(\Omega) = \frac{1}{A^2} \sum_n \int \frac{d\omega}{2\pi} d\omega_{kL} d\omega_{kR} \times T^i_R(\omega_{kL}, \omega_{kR}) \sum_{\sigma} [\bar{\psi}_{1\sigma}(\omega, k_{L,x}) \psi_{2\sigma}(\Omega + \omega + 2\Delta \mu, k_{R,x}) + \bar{\psi}_{2\sigma}(\omega, k_{L,x}) \psi_{1\sigma}(\Omega + \omega + 2\Delta \mu, k_{R,x})].
\]
Next, the total current can be calculated by
\[
I(t) = \int \frac{d\Omega}{2\pi} e^{i\Omega t} I(\Omega),
\]
where $I(\Omega)$ is given by
\[
I(\Omega) = \frac{i}{2} \left. \frac{\partial Z}{\partial A^i} \right|_{A^i=0} = I_F(\Omega) + I_B(\Omega).
\]
To order of $T^2_{F,B}$, the currents can be calculated
\[
I_F(\Omega) = \frac{1}{2} \left( \left| J^i_F(\Omega) \right|^2 - \left| J^i_B(\Omega) \right|^2 \right).
\]
\[
I_B(\Omega) = \left( J^i_F(\Omega) J^i_B(\Omega) \right).
\]
To calculate the correlation functions in the above equations we adopt the approximations: $\langle \bar{\psi}_{1\sigma} \psi_{1\sigma} \rangle \approx \langle \bar{\psi}_{1\sigma} \psi_{1\sigma} \rangle$ and $\langle \bar{\psi}_{1\sigma} \psi_{1\sigma} \rangle \approx \langle \bar{\psi}_{1\sigma} \psi_{1\sigma} \rangle$, where all the two-point correlation functions are the single particle propagators renormalized with self-energy within the NSR scheme. A straightforward calculation yields
\[
I_F(t) = 2 \alpha_F e_F \int \frac{d\omega}{2\pi} \frac{d\epsilon_L}{\sqrt{\epsilon_L}} \frac{d\epsilon_R}{\sqrt{\epsilon_R}} \times \Theta(\epsilon_L - n\omega_F - V_g) \Theta(\epsilon_R - n\omega_F - V_g) A^F_L(\omega, \sqrt{2m\epsilon_L}) A^F_R(\omega + \Delta \mu, \sqrt{2m\epsilon_R}) [n_F(\omega) - n_F(\omega + \Delta \mu)],
\]
\[
I_B(t) = 2 \alpha_B e_F \int \frac{d\omega}{2\pi} \frac{d\epsilon_L}{\sqrt{\epsilon_L}} \frac{d\epsilon_R}{\sqrt{\epsilon_R}} \times \Theta(\epsilon_L - n\omega_F - V_g) \Theta(\epsilon_R - n\omega_F - V_g) A^B_L(\omega, \sqrt{4m\epsilon_L}) A^B_R(\omega + 2\Delta \mu, \sqrt{4m\epsilon_R}) [n_B(\omega) - n_B(\omega + 2\Delta \mu)].
\]
