Abstract: Laparoscopic resection of gastric wall tumor is commonly performed nowadays. The exact surgical procedure was decided according to the location, size and morphology of the tumor. In this video, we performed a laparoscopic resection of a 5 cm tumor located at distal posterior gastric wall near the greater curvature. Technical consideration was discussed.

Keywords: Laparoscopic; gastric wall tumor; resection; suture repair

Patients

A 57-year-old gentleman, with good past health, presented with intermittent mild upper abdominal pain for 1 year. CT scan abdomen was performed and showed a 4 cm × 5 cm tumor near distal body of stomach. Upper endoscopy revealed a submucosal tumor at posterior wall of distal greater curve and it appeared to originate from muscularis propria layer on endoscopic ultrasound.

Pre-operative preparation

The patient was kept fasted for 6 hours prior to surgery. The operation was performed under general anesthesia with endotracheal intubation. A Fr 14 gastric decompression tube and urinary catheter were placed. Prophylactic cefuroxime 1.5 g was administrated intravenously on induction.

Equipment preference card

High definition laparoscopic video system, pneumoperitoneum system, ultrasonic dissector, laparoscopic instruments including atraumatic graspers, needle holder, scissors, 4–0 maxon suture and plastic specimen bag were prepared.

Procedure

The patient was placed in a supine position with legs...
separated. The chief surgeon stood between the legs. The assistant stood on the left side and the camera operator stood on the right side of the patient. A 10-mm trocar was placed in subumbilical region and pneumoperitoneum was created. The intra-abdominal pressure was maintained at 12 mmHg. The other trocar sites including a 12-mm trocar at right upper quadrant mid-clavicular line, two 5-mm trocars at left upper quadrant mid-clavicular line and anterior axillary line are shown in Figure 1.

Laparoscopic assessment was performed and a tumor bulge was identified in distal stomach. The greater omentum was dissected free from the greater curvature of stomach by ultrasonic dissector. The lesser sac was entered and the posterior wall of distal stomach and antrum was exposed. A 5-cm tumor was noted arising from posterior gastric wall near greater curvature. Gastrostomy was made with ultrasonic dissector next to the tumor. Circumferential full thickness resection of gastric tumor was performed. The tumor was immediately put into a plastic specimen bag. Hemostasis of gastric wall was secured. The gastrostomy was suture repaired with 4-0 maxon in continuous manner. (Figure 2) The peritoneal cavity was cleansed with warm normal saline. The specimen was then retrieved via subumbilical trocar site after enlargement.

Role of team members

- Chief surgeon: Dr. Xuefei Yang;
- Assistant: Dr. Fion S. Chan;
- Camera operator: Dr. Li Jiang;
- Anesthetist: Dr. Xinhe Liu;
- Scrub nurse: Kaisong Hou.

Post-operative management

The patient was prescribed intravenous cefuroxime for 1 day. Gastric tube was removed on day 1 and fluid diet was commenced on day 3 after the operation. The patient was fit for discharged on day 4 with esomeprazole for 2 weeks.

Histopathological examination of resected specimen confirmed the diagnosis of schwannoma. Immunology exam showed S-100 diffusely strong positive, CD34 focal weak positive, SMA negative, Desmin negative, CD117 focal suspected positive, ki67 about 1–4% incidental mitotic count.

Tips, tricks and pitfalls

Proper exposure of tumor is sometimes difficult for tumor located at posterior wall of stomach. This is facilitated by transection of greater omentum and exposure of lesser sac.

Resection of tumor with linear stapler is sometimes performed for pedunculated gastric wall tumor with extra-gastric extension. This minimizes the risk of tumor seeding and peritoneal contamination by gastric content. However, this is not suitable for tumor with intra-gastric extension or involvement of a wide area of gastric wall. Otherwise, incomplete resection of tumor may result or more extensive...
resection of gastric wall adjacent to the tumor is inevitable. Furthermore, resection by linear stapler is not suitable for tumor located along gastric lesser curve or close to cardia and pylorus.

Gastrostomy followed by resection of gastric tumor with clear margin was performed in our patient due to the wide area of gastric wall involvement. Ultrasonic dissector, with good hemostatic performance for gastric wall vessels, is used to resect localized gastric wall tumor. Careful and gentle manipulation of tumor during dissection should be practiced to avoid breakage of tumor capsule and rupture of the tumor. Immediate placement of tumor in a plastic specimen bag and adequate peritoneal lavage were performed to reduce risk of tumor seeding.

Suture repair of gastrostomy can be difficult without good exposure and close cooperation between the chief surgeon and assistant. Omental fat next to the edge of gastrostomy should be dissected free to facilitate proper placement of sutures. Gentle pull of the suture material is very important especially when the suture repair is performed in a continuous manner.
