Introduction: Fibroblast growth factor 21 (FGF21) plays an important role in glucose and
lipid metabolism. Elevated blood FGF21 level is associated with obesity, diabetes and
atherosclerosis. We therefore investigated its relationship with blood pressure.
Methods: We measured FGF21 in the plasma of 1921 participants (891 men, 1030 women;
52±12 years) taken at the start of the Hong Kong Cardiovascular Risk Factor Prevalence
Study (CRISPS) using an enzyme-linked immunosorbent assay (Antibody & Immunoassay
Services, University of Hong Kong). The log of FGF21 level was analysed for relationship
with systolic and diastolic blood pressure (BP) at baseline and at the 5-year follow-up.
Results: Plasma FGF21 level was 224.3±7.4 in men and 214.1±7.1 pg/ml in women. It
correlated significantly (p<0.001) with age (r=0.30), waist circumference (r=0.31), systolic
BP (r=0.32), diastolic BP (r=0.22), triglyceride (r=0.41), HDL-C (r=-0.27), fasting blood
glucose (r=0.27) and hsCRP (r=0.27). In multivariate analysis, FGF21 was related to systolic
and diastolic blood pressure at baseline (β=0.076, p<0.001 and β=0.074, p=0.001
respectively) and to diastolic blood pressure at follow-up (β=0.06, p=0.025).
Conclusions: FGF21 level in blood is related to systolic and diastolic blood pressure,
independent of age, obesity, lipids and blood glucose. FGF21 is related to the components of
the metabolic syndrome and may have a pathophysiological role in hypertension.
