Abstract

This paper deals with the fault detection filter design problem for linear time invariant time-delay systems with unknown input. The core of our study is to a) take the behavior of delayed state and measurement into consideration when the observer-based fault detection filter is constructed; b) solve the formulated fault detection filter design problem by combining of using the left eigenstructure assignment approach and $H_\infty$ optimization technique. Through a suitable choice of the filter gain matrices and residual weighting matrix, the residual can be completely decoupled from the delay-free unknown input, while the influence of the delayed unknown input on residual is minimized in the sense of $H_\infty$ norm. Numerical simulation is used to illustrate the efficiency of the proposed method.

Key words. Eigenstructure assignment, fault detection, filter, $H_\infty$ optimization, time delay

1 Introduction

In the past three decades, many significant results concerning fault detection and isolation (FDI) problems have been developed, see e.g [1, 3, 4, 10, 11] and references therein. However, most of the achievements are for delay-free systems. Although, time delay is an inherent characteristic of many physical systems, such as rolling mills, chemical processes, water resources, biological, economic and traffic control systems, only few researches on FDI have been carried out for them [2, 5, 6, 7, 9]. Note that Jean-Yves and Wohida [5] study only the fault isolation problem for a kind of discrete-time system; Jiang \textit{et al.} [6] deal with the nominal case fault identification (without considering the influence of model uncertainty and unknown inputs); Liu and Frank [9] formulate the fault detection filter (FDF) design problem as a two-objective non-linear programming problem where no analytic solution can be constructed in general; Jiang \textit{et al.} [7] extends the results in [9] to the discrete-time case. The authors' earlier study in [2] has also developed an FDF design approach based on $H_\infty$-filtering, but the most important and difficult issue concerning the selection of a so-called reference residual model has not been successfully solved. An efficient way to tackle the fault detection problem for time-delay systems is as yet to be developed.

The main focus of this paper is to deal with the FDF design problem for LTI time-delay systems with unknown input. An FDF will be developed such that the influence of unknown input on residual is to be minimized to increase the robustness to unknown input, while the effect of fault is to be maximized to enhance the sensitivity to fault. The basic idea of our study is first to construct a new form of observer-based FDF and, based on which, to decompose the generated residual into three parts: the effect of delay-free unknown input, the influence of delayed unknown input and past information of the fault, the contribution of current faults on the residual. Then, by decoupling the residual from the delay-free unknown input and at the same time minimizing the influence of the delayed unknown input on it, to achieve perfect performance of FDI. By a combination of two often used FDI schemes, that is, eigenstructure assignment approach and $H_\infty$ optimization techniques, a new FDF design method for time-delay system is developed in this paper.
2 Problem Formulation

We focus our attention on the FDF design problems for LTI time-delay systems, which are governed by

\[ \dot{x}(t) = Ax(t) + \sum_{i=1}^{N} A_i x(t - \tau_i) + Bu(t) + B_d f(t) \tag{1} \]

\[ y(t) = Cx(t) + Du(t) + D_f f(t) \tag{2} \]

\[ z(t) = 0 \quad (t < 0) \]

where \( x \in \mathbb{R}^n \) is the state vector, \( u \in \mathbb{R}^p \) the control input vector, \( d \in \mathbb{R}^m \) the unknown input vector, \( f \in \mathbb{R}^l \) the fault to be detected and isolated. \( A, B, C, D, B_f, B_d, D_f, D_d \) are known matrices with appropriate dimensions. It is assumed that system (1)-(2) is asymptotically stable; \( d \) is \( L_2 \)-norm bounded; fault is detectable; \( \tau_i > 0 \) (\( i = 1, 2, \ldots, N \)) denote the constant time delays; \( A_i \) are known matrices with appropriate dimensions.

In this paper, the following observer-based FDF is proposed

\[ \dot{x}(t) = Ax(t) + \sum_{i=1}^{N} A_i x(t - \tau_i) + Bu(t) + H(y(t)) \tag{3} \]

\[ \dot{y}(t) = Cx(t) + Du(t) \tag{4} \]

\[ r(t) = V(y(t) - \dot{y}(t)) \tag{5} \]

where \( \dot{x} \in \mathbb{R}^n \) and \( \dot{y} \in \mathbb{R}^n \) are state and measurement estimation vector respectively. \( r \) is the generated residual. Filter gain matrices \( H, H_i \) (\( i = 1, 2, \ldots, N \)) and weighting matrix \( V \in \mathbb{R}^{p \times q} \) are parameters to be designed.

Denote \( e_x(t) = x(t) - \dot{x}(t) \), then the dynamics of the FDF for LTI time-delay systems (1)-(2) can be expressed as

\[ \dot{e}_x(t) = (A - HC)e_x(t) + \sum_{i=1}^{N} (A_i - H_i C) e_x(t - \tau_i) \]

\[ + B_d d(t) + (B_f - HD_f) f(t) \tag{6} \]

\[ r_f(s) = V(C(sI - A + HC - \sum_{i=1}^{N} (A_i - H_i C)e^{-s\tau_i})^{-1} \times B_d d(s) \]

\[ \times ((B_f - HD_f) + D_f - \sum_{i=1}^{N} H_i D_f e^{-s\tau_i}) f(s) \tag{7} \]

The main tasks of ideal FD system design is to select \( H, H_i \) (\( i = 1, 2, \ldots, N \)) and \( V \) such that residual generator (6)-(7) is asymptotically stable, and the generated residual satisfies

\[ r(s) = 0, \quad \text{if } f(s) = 0 \tag{8} \]

\[ r(s) \neq 0, \quad \text{if } f(s) \neq 0 \tag{9} \]

Obviously, for the \( L_2 \)-norm bounded unknown input \( d \), a necessary condition to achieve (11)-(12) is

\[ VC(sI - A + HC - \sum_{i=1}^{N} (A_i - H_i C)e^{-s\tau_i})B_d = 0 \tag{10} \]

\[ V(C(sI - A + HC - \sum_{i=1}^{N} (A_i - H_i C)e^{-s\tau_i})^{-1} \times ((B_f - HD_f) + D_f - \sum_{i=1}^{N} H_i D_f e^{-s\tau_i}) f(s) \neq 0 \tag{11} \]

However, the existence conditions for suitable matrices \( H, H_i \) and \( V \) to satisfy (13)-(14) are usually too strong to be satisfied. This paper focuses on the study of FD in which totally decoupling of \( r \) from \( d \) may be impossible. Hence, the main task in an FDF design consists of a trade-off between maximizing the influence of \( r_f \) to increase the sensitivity to fault and minimizing that of \( r_d \) to enhance the robustness to unknown input by selecting \( H, H_i \) and \( V \) appropriately.

3 Design of Fault Detection Filter

First, re-write the FDF transfer function expression in (8) into the following form

\[ r(s) = Gr_d d(s) + \sum_{i=1}^{N} (G_{s \tau_i} G_{s \tau_i} d)(s) d(s) \]

\[ + G_{s \tau_i} f(s) e^{-s\tau_i} + G_{s \tau_i} f(s) \tag{12} \]

where

\[ Gr_d(s) = VC(sI - A + HC)^{-1} B_d \]

\[ G_{s \tau_i}(s) = VC(sI - A + HC)^{-1} (A_i - H_i C) \]
\[ G_r(s) = V(C(sI - A + HC)^{-1}(B_f - HD_f) + D_f) \]
\[ G_{rr_t}(s) = VC(sI - A + HC)^{-1}H_tD_f \]
\[ G_{e_f}(s) = (sI - A + HC - \sum_{i=1}^{N}(A_t - H_tC)e^{-\sigma_r t})^{-1} \]
\[ \times (B_f - HD_f) + D_f - \sum_{i=1}^{N}H_tD_fe^{-\sigma_r t} \]
\[ G_{e_d}(s) = (sI - A + HC - \sum_{i=1}^{N}(A_t - H_tC)e^{-\sigma_r t})^{-1} \]
\[ \times B_de^{-\sigma_r t} \]

Notice that the above generated residual is linearly divided into three parts: the effects of delay-free unknown input \( G_{rd}(s)d(s) \); the influence of delayed unknown input and fault \( G_{rr_t}(s)d(s) \) and the main contribution of fault on residual \( G_{e_f}(s)f(s) \). This paper formulates the FDF design problems as finding suitable filter gain matrices \( H_i \) (\( i = 1, 2, \ldots, N \)) and weighting matrix \( V \) such that

- first, to null the entries in the transfer function matrix between the residual and the delay-free unknown input, that is, to satisfy
  \[ G_{rd}(s) = VC(sI - A + HC)^{-1}B_d = 0 \] (16)

by suitably selecting \( H \) and \( V \), which can be handled by applying eigenstructure assignment approach. While the other requirements, such as the sensitivity of residual to fault, the influence attenuation of delayed unknown input as well as the FDF stability, can be guaranteed by using the design freedom of \( H \) and \( V \) as well as the furthermore designing of \( H_i \) (\( i = 1, 2, \ldots, N \)).

- based on \( H \) and \( V \) obtained in first step, to find \( H_i \) such that system (6)–(7) is asymptotically stable and the influence of delayed unknown input is minimized. It can be achieved by minimizing the \( H_\infty \) norm of transfer function from unknown input \( d \) to \( \sum_{i=1}^{N}G_{rr_t}(s)e^{-\sigma_r t}e_c(s) \), that is,
  \[ \min_{H_i} J \] (17)

where
  \[ J = \left\| \sum_{i=1}^{N}G_{rr_t}(s)G_{e_d}(s) \right\|_\infty \]

or loosely by making \( \gamma \) \( (> 0) \) small in terms of the feasibility of
  \[ \left\| \sum_{i=1}^{N}G_{rr_t}(s)G_{e_d}(s) \right\|_\infty < \gamma \] (18)

4 Main Results

4.1 Delay-free Unknown Input Decoupling

One of the most important unknown input decoupling FDI approach is the eigenstructure assignment, in which some left eigenvectors of the observer are assigned, to be orthogonal to the unknown input distribution directions. In this way, the residual can be made robust against the unknown input \([11]\). For our purpose, the following results of left eigenstructure assignment in \([11]\) are used to determine \( H \) and \( V \).

**Lemma 1** \([11]\) A necessary condition to satisfy (16) is that there exists a matrix \( V \) to achieve

\[ VCB_d = 0 \] (19)

**Lemma 2** \([11]\) The sufficient conditions for satisfying the unknown input de-coupling requirement (16) are

1. \( VCB_d = 0 \).
2. All rows of the matrix \( VC \) are left eigenvectors of \((A - HC)\) corresponding to any eigenvalues.

Just as mentioned in \([11]\), \( V \) can be determined based on Lemma 1, while the independent row number of \( V \) is normally chosen as

\[ p_v = q - \text{rank}(CB_d) < q \]

Lemma 2 indicates that the row of \( VC \) can be used as the \( p_v \) left eigenvectors of \((A - HC)\) corresponding to some eigenvalues, which are chosen according to the desired dynamic property of the residual. The remaining \((n - p_v)\) left eigenvectors can be chosen so that the effect of the most important factor of fault \( G_{r_f}(s)f(s) \), is maximized. For the detailed principles, the solvability condition and the design procedures of \( V \) and \( H \), interested readers are referred to \([11]\).
4.2 $H_i$ Design via $H_\infty$ Optimization

With the above obtained matrices $H$ and $V$, residual generator (15) becomes

$$ r(s) = \sum_{i=1}^{N} (G_{r,r_i}(s) e_k(s) - G_{y,y_i}(s) f(s)) e^{-s \tau_i} + G_{y,y_i}(s) f(s) $$

(20)

The remaining task of FDF design for LTI time-delay systems (1)-(2) is to determine matrices $H_i$ such that the residual generator is asymptotically stable and the requirement (17) or (18) is satisfied. Denote

$$ N_i(t) = \sum_{i=1}^{N} (A_i - H_i C) e_x(t - \tau_i) + B_d d(t) + (B_f - H D_f) f(t) $$

which can also be expressed as

$$ N_i(t) = V C \zeta(t) $$

(23)

where $\zeta(t) \in \mathbb{R}^n$ is an auxiliary state vector. Then matrices $H_i$ are determined according to find $H_i$ that system (21)-(23) is asymptotically stable and satisfies

$$ \|G_{r,e}(s)\|_\infty < \gamma $$

(24)

with $\gamma$ as small as possible in terms of the feasibility of (24), where

$$ G_{r,e}(s) = \sum_{i=1}^{N} V C (s I - A + H C)^{-1} (A_i - H_i C) $$

$$ \times (s I - A + H C + \sum_{i=1}^{N} (A_i - H_i C) e^{-s \tau_i})^{-1} B_d e^{-s \tau_i} $$

Now we are in a position to solve $H_i$, the following lemma is required.

Lemma 3 [8] Given $\gamma > 0$ and system model

$$ \dot{x}(t) = A x(t) + \sum_{i=1}^{N} A_i x(t - \tau_i) + B w(t) $$

$$ z(t) = C x(t) + D w(t) $$

$$ x(t) = 0 (t \leq 0) $$

if there exist matrices $P > 0, Q > 0$ and $R_i > 0 (i = 1, 2, \ldots, N)$ such that the LMI

$$ \begin{bmatrix} \Gamma_1 & PA_1 & \cdots & PA_N & PB & C^T \\ A_i^T P & -R_i & 0 & \cdots & 0 \\ \vdots & 0 & \ddots & \cdots & \vdots \\ A_N^T P & 0 & \cdots & -R_N & 0 \\ B^T P & 0 & \cdots & 0 & -\gamma^2 I & D^T \\ C & 0 & 0 & 0 & D & -I \end{bmatrix} < 0 $$

holds, where

$$ \Gamma_1 = A^T P + PA + \sum_{i=1}^{N} R_i $$

then the system under consideration is asymptotically stable and

$$ \|G_{e,w}(s)\|_\infty < \gamma $$

For some given $\gamma > 0$, the following theorem provides a sufficient solvability condition and the solution of $H_i (i = 1, 2, \ldots, N)$ to ensure the asymptotic stability of (21)-(23) and $H_\infty$ norm constraint (24).

Theorem 4 Given filter gain matrix $H_i$, weighting matrix $V$ and constant $\gamma > 0$, if there exist matrices $P > 0, \tilde{R}_i > 0$ and $H_i (i = 1, 2, \ldots, N)$, such that the matrix inequality

$$ \begin{bmatrix} X \dot{A}^T + \dot{A} X & \dot{A}_1 - \tilde{H}_i \tilde{C}_1 & \cdots & \dot{A}_N - \tilde{H}_N \tilde{C}_1 \\ \dot{A}_{1}^T - \tilde{C}_1^T \tilde{H}_1^T & -\tilde{R}_1 & 0 & 0 \\ \vdots & 0 & \ddots & \vdots \\ \dot{A}_{N}^T - \tilde{C}_N^T \tilde{H}_N^T & \cdots & \cdots & -\tilde{R}_N \\ \dot{B}_d & \cdots & \cdots & 0 \\ \tilde{C}_2 X & \cdots & \cdots & \cdots \\ X & \cdots & \cdots & \cdots \\ X & 0 & 0 & 0 \\ -\gamma^2 I & \cdots & \cdots & \cdots \\ 0 & -I & \cdots & \vdots \\ \vdots & \ddots & \cdots & 0 \\ 0 & \cdots & -\tilde{R}_1^{-1} & \cdots \\ 0 & \cdots & \cdots & 0 \\ 0 & 0 & 0 & -\tilde{R}_N^{-1} \end{bmatrix} < 0 $$

(25)
holds, then system (21)-(23) is asymptotically stable and the $H_{\infty}$ norm constraint (24) is satisfied, where
\begin{align*}
\hat{A} &= \begin{bmatrix} A - HC & 0 \\ 0 & A - HC \end{bmatrix} \\
\hat{A}_i &= \begin{bmatrix} A_i & 0 \\ 0 & A_i \end{bmatrix}, \quad \hat{B}_d = \begin{bmatrix} B_d \\ 0 \end{bmatrix} \\
\hat{H}_i &= \begin{bmatrix} H_i \\ H_i \end{bmatrix}, \quad \hat{C}_1 = \begin{bmatrix} C \\ 0 \end{bmatrix} \\
\hat{C}_2 &= \begin{bmatrix} 0 \\ VC \end{bmatrix}
\end{align*}

\[ (26), (27), (28), (29) \]

\[ (ii) \] To obtain such matrices $\hat{H}_i$ that $\gamma$ is made small in terms of the feasibility of (24), a repeatedly use of Theorem 1 is also necessary;
\[ (iii) \] To satisfy the solvability condition of $\hat{H}_i$ and ensure satisfactory FD property, the design freedom in $H$ and $V$ can be exploited.

5 Numerical Example

To illustrate the effectiveness of the proposed approach, a numerical example is given in this section. Consider LTI time-delay system (1)-(2) with
\begin{align*}
A &= \begin{bmatrix} 0 & 3 & 4 \\ 1 & 2 & 3 \end{bmatrix}, \quad A_1 = \begin{bmatrix} 0 & 0.1 & 0 \\ 0 & 2 & 5 \end{bmatrix} \\
B_f &= \begin{bmatrix} 1 \\ 0.5 \\ 0.2 \end{bmatrix}, \quad B_d = \begin{bmatrix} 1 \\ 0 \end{bmatrix} \\
C &= \begin{bmatrix} 0 & 1 \\ 0 & 0.1 \end{bmatrix}, \quad D_f = \begin{bmatrix} 0.1 \\ 0.1 \end{bmatrix}
\end{align*}

\[ (30), (31) \]

Since the control input has no influence on the designed residual, it is not considered in this example. According to the proposed design method, the following results are obtained:
\begin{align*}
\gamma &= 0.05, \quad V = \begin{bmatrix} 0 & 1 \end{bmatrix} \\
H &= \begin{bmatrix} 0 & 0.1 \\ 9 & 7 \end{bmatrix}, \quad H_1 = \begin{bmatrix} 0 & 1 \\ 2 & 0.5 \end{bmatrix}
\end{align*}

\[ (32) \]

Suppose the unknown input $d$ is band-limited white noise with unit power given in Fig. 1. Two fault signals $f_1$ and $f_2$ are simulated with unit amplitude over time interval $[5, 10]$ sec. Fig. 2 and Fig. 3 respectively show the generated residual signal $r(t)$ for $f = [f_1 \ 0]^T$ and $f = [0 \ f_2]^T$. It can be seen that the generated residual shows good performance despite the unknown input.

![Fig. 1. Unknown input d(t)](image-url)
6 Conclusion

In this paper, the fault detection filter design problem for LTI time delay systems with unknown input is studied. By combining use left eigenstructure assignment FDI and $H_\infty$ optimization techniques, a novel approach of FDF design for LTI time-delay systems with unknown input has been proposed, in which complete decoupling of residual from delay-free unknown input is achieved by applying eigenstructure assignment FDI approach, while the influence of delayed unknown input is minimized in the sense of the $H_\infty$ norm. A simulation example is presented to demonstrate the achieved results.
