(Received 3 March 2007; published 9 July 2007)

We explore a dynamic signature of quantum phase transition (QPT) in an isotropic Lipkin-Meshkov-Glick (LMG) model by studying the time evolution of a central qubit coupled to it. We evaluate exactly the time-dependent purity, which can be used to measure quantum coherence, of the central qubit. It is found that distinctly different behaviors of the purity as a function of the parameter reveal clearly the QPT point in the system. It is also clarified that the present model is equivalent to an anti–Jaynes-Cummings model under certain conditions.

I. INTRODUCTION

Quantum phase transitions (QPTs) [1] in spin systems, e.g., the XY model [2], the Lipkin-Meshkov-Glick (LMG) model [3], and the Dicke model [4], have aroused much interest in recent years. Most of these efforts have addressed possible connections of quantum entanglement measures, such as the concurrence, the entanglement entropy, and the connection between the current model and an anti-JC model is established. Section VI presents our summary and conclusion.

II. LIPKIN-MESHKOV-GLICK (LMG) MODEL FOR QUANTUM PHASE TRANSITION

We consider a central qubit (two-level system) that couples to a multispin bath, which is described by the LMG model [3]

\[ H_B = -\frac{\lambda}{N} \sum_{i<j} (\sigma_i^x \sigma_j^x + \gamma \sigma_i^y \sigma_j^y) - \sum_{i=1}^{N} \sigma_i^z, \]

where \( \sigma_i^\alpha, \alpha=x,y,z \) (i=1,2,\ldots,N) are the Pauli matrices of the \( i \)th spin, \( \lambda/N \) denotes the coupling strength, which is inversely proportional to the spin number \( N \). This Hamiltonian contains long-range interactions, i.e., every spin in the bath interacts with all the others. In the isotropic case, the Hamiltonian is diagonal in the Dicke representation

\[ H_B = -\frac{2\lambda}{N} \left[ J_N^N - (J_N^N)^2 - \frac{N}{2} \right] - 2J_N^N, \]

and the ground state of \( H_B \) lies in the subspace spanned by the Dicke states \( |N/2,M\rangle, M=-N/2,\cdots,N/2| \) [13]. Here, \( s = \tilde{\sigma}/2, J_{N/2} = \frac{1}{2} \sum_{i=1}^{N} \sigma_i^\alpha \), and

\[ J_N^N \begin{pmatrix} N/2, M \end{pmatrix} = \frac{N}{2} \left( \frac{N}{2} + 1 \right) \begin{pmatrix} N/2, M \end{pmatrix}. \]

The eigenenergy corresponding to \( |N/2, M\rangle \) is \( 2\lambda M^2/N - 2M - \lambda N/2 \). Hence the ground state \( |G\rangle \) is \( \lambda \) dependent [14], i.e.,
\[ |G\rangle = \begin{cases} \frac{N}{2} & (0 < \lambda < 1), \\ \frac{N}{2} J(\lambda) & (\lambda > 1), \end{cases} \]  

where \( J(\lambda) \) is the integer nearest to \( N/2\lambda \). Equation (4) indicates that there is a level crossing at \( \lambda = 1 \), which implies a QPT at \( \lambda = 1 \) [1]. In the phases above and below \( \lambda = 1 \) the properties of the ground state are significantly different, or the ground state of the system on two sides of \( \lambda = 1 \) has different symmetries. Hence the point \( \lambda = 1 \) is also a symmetry breaking point [14,15]: When \( 0 < \lambda < 1 \), the ground state of the bath is unique and fully polarized in the magnetic field direction, and thus the bath is in a symmetry broken phase; when \( \lambda > 1 \), the ground state is infinitely degenerate and thus the bath is in a symmetric phase. We below elaborate how the dynamic evolution of the purity of \( |\Psi\rangle \) (a measure of quantum coherence) depends on the coupling strength between the central qubit and the bath; in particular, we observe that the purity shows distinctly different behaviors in the two phases, which may be used to reveal the QPT point in the bath.

III. DYNAMICS OF A CENTRAL QUBIT COUPLED TO AN ISOTROPIC LMG MODEL

A qubit-bath model is described by the total Hamiltonian \( H = H_B + H_S + H_{SB} \) [17,18], where \( H_S = -2x_S \) is the free Hamiltonian of the central qubit \( S \). \( H_{SB} \) denotes the coupling between \( S \) and the bath \( B \). Specifically, the total Hamiltonian can be written as

\[ H = -\frac{\lambda}{N} \sum_{i<j}^N (\sigma_i^x \sigma_j^x + \sigma_i^y \sigma_j^y) - \sum_{i=1}^N \sigma_i^z + \lambda' \sum_{i=1}^N (\sigma_i^x \sigma^z + \sigma_i^y \sigma^z) - \sigma^z, \]

where \( \sigma^a \), \( \sigma^x, \sigma^y, \sigma^z \), are the Pauli operators of the central qubit; \( \lambda' \) is the coupling strength between the central qubit and the bath. In the Dicke representation, the above Hamiltonian can be rewritten as

\[ H = -\frac{\lambda}{N} [J_N^x J_N^x + J_N^y J_N^y - N] - 2J_N^z - 2\lambda'(s^z J_N^x + s^{-}\rightarrow J_N^y) - (2s_z), \]

where \( J_N^x = J_N^x + iJ_N^y \) and \( s_z = s^z \rightarrow i s^y \) are the ladder operators of the \( N \)-spin bath and the central qubit, respectively. For simplicity, we denote the two eigenstate of the central qubit as \( |\uparrow\rangle = |1/2, 1/2\rangle \) and \( |\downarrow\rangle = |1/2, -1/2\rangle \), and \( s_z |\uparrow\rangle = |\downarrow\rangle /2 \). In an invariant subspace \( \mathcal{H}_M \) of \( H \) spanned by the ordered basis vector \( \{ |N/2, M\rangle \otimes |\uparrow\rangle, |N/2, M+1\rangle \otimes |\downarrow\rangle \} \), the total Hamiltonian can be expressed as a quasi-diagonal matrix with the diagonal blocks

\[ H_M = \begin{bmatrix} \alpha & \xi \\ \xi & \beta \end{bmatrix}, \]

where

\[ \alpha = -\frac{\lambda}{2N}[N^2 - 4M^2] - 2M - 1, \]

\[ \beta = -\frac{\lambda}{2N}[N^2 - 4(M+1)^2] - 2(M+1) + 1, \]

\[ \xi = -\lambda' \sqrt{N(N+2) - 4M(M+1)}. \]

A straightforward calculation determines the two eigenvalues \( x_1 \) and \( x_2 \) of \( H_M \) as

\[ x_1 = \frac{1}{2} \left[ (\alpha + \beta) + \sqrt{(\alpha - \beta)^2 + 4\xi^2} \right], \]

\[ x_2 = \frac{1}{2} \left[ (\alpha + \beta) - \sqrt{(\alpha - \beta)^2 + 4\xi^2} \right], \]

and the eigenstate \( |\Psi_1\rangle \) corresponding to \( x_1 \) is

\[ |\Psi_1\rangle = a \begin{bmatrix} N/2, M \rangle \otimes |\uparrow\rangle + b \begin{bmatrix} N/2, M+1 \rangle \otimes |\downarrow\rangle \end{bmatrix}, \]

where

\[ \begin{align*} a &= \frac{\xi}{\sqrt{(\alpha-x_1)^2 + \xi^2}}, \\
 b &= \frac{x_1 - \alpha}{\sqrt{(\alpha-x_1)^2 + \xi^2}}. \end{align*} \]

We would like to point out that, in the symmetric phase, all \( x_1, x_2, a, \) and \( b \) are functions of \( \lambda(\lambda) \), i.e., \( F = F(\lambda) \) with \( F = x_1, x_2, a, \) and \( b \). The dynamic evolution operator \( U(t) = \text{exp}[-iHt] \) in the subspace \( \mathcal{H}_M \) can be expressed in terms of \( x_1, x_2, a, \) and \( b \)

\[ U_M(t) = \begin{bmatrix} a^2 e^{-ix_1 t} + b^2 e^{-ix_2 t}, & ab(e^{-ix_1 t} - e^{-ix_2 t}) \\
 ab(e^{ix_1 t} - e^{ix_2 t}), & b^2 e^{-ix_1 t} + a^2 e^{-ix_2 t} \end{bmatrix}. \]

We wish to mention that the above dynamic evolution (11) is valid only for the cases when \( -N/2 \leq M < N/2 \), because \( \{|N/2, M\rangle \otimes |\uparrow\rangle, |N/2, M+1\rangle \otimes |\downarrow\rangle \} \) is a two-dimensional invariant subspace for these cases. But for the case \( M = N/2 \), \( \{|N/2, M\rangle \otimes |\uparrow\rangle\} \) is a one-dimensional invariant subspace, i.e., \( |N/2, N/2\rangle \otimes |\uparrow\rangle \) is an eigenstate of the total Hamiltonian (6), and its corresponding eigenenergy is \( -(N+1) \). Thus the dynamic evolution of this state \( |N/2, N/2\rangle \otimes |\uparrow\rangle \) is different from Eq. (11). We will discuss this point in the next section.

IV. PURITY OF THE CENTRAL QUBIT AS A WITNESS OF QUANTUM PHASE TRANSITION

Based on the above results, we now solve the Schrödinger equation that describes the dynamics of the purity of the central qubit. To highlight the influence of the QPT of the bath on the coupled central qubit, it is assumed that the bath and the central qubit are initially in the ground state \( |G\rangle \) (4) and a pure superposition state \( c_1 |\uparrow\rangle + c_2 |\downarrow\rangle \), respectively.
The evolution of the total system (the bath plus the central qubit) is
\[ |\Psi_{N+1}(t)\rangle = e^{-it\hat{H}}|G\rangle \otimes (c_1|\uparrow\rangle + c_2|\downarrow\rangle), \]
and the reduced density matrix of the central qubit is
\[ \rho_\text{c}^\text{e}(t) = \text{Tr}_\text{B}|\Psi_{N+1}(t)\rangle\langle\Psi_{N+1}(t)|, \]
where \( \text{Tr}_\text{B} \) means tracing out the degree of freedom of the bath.

The purity \( P \) of the central qubit is defined as
\[ P = \text{Tr}_\text{c}(\rho_\text{c}^\text{e}(t))^2 = [\rho_{\uparrow\uparrow}^\text{c}(t))^2 + [\rho_{\downarrow\downarrow}^\text{c}(t))^2 + 2|\rho_{\uparrow\downarrow}^\text{c}(t)|^2, \]
which can be used to measure the quantum coherence. For a pure state, the purity equals to unity, while for a mixed state the purity is less than unity. The decay of purity indicates the loss of quantum coherence [16].

A. Purity of the central qubit in two phases

1. Symmetric phase

When \( \lambda > 1 \), the bath is in the symmetric phase and \( I(\lambda) = N/2 \). As mentioned above, we can apply the evolution matrix (11) to obtain the reduced density matrix \( \rho_\text{c}^\text{e}(t) \) of the central qubit with the matrix elements defined by
\[ \rho_{\uparrow\uparrow}^\text{c}(t) = \sqrt{|c_1|^2 g(\lambda, t)} + |c_2|^2 h(\lambda, t)), \]
\[ \rho_{\downarrow\downarrow}^\text{c}(t) = \sqrt{|c_1|^2 g(\lambda, t)} + |c_2|^2 h(\lambda, t)), \]
\[ |\rho_{\uparrow\downarrow}^\text{c}(t)| = \sqrt{|c_1|^4 g(\lambda, t)} \times f(\lambda, t) = |\rho_{\text{c}}^\text{e}(t)|, \]
where
\[ f(\lambda, t) = a^4 + b^4 + 2a^2b^2 \cos[(x_1 - x_2)t], \]
\[ g(\lambda, t) = (a')^4 + (b')^4 + 2(a')^2(b')^2 \cos[x_1'(x_2 - x_2)t], \]
\[ h(\lambda, t) = 2(a')^2(b')^2[1 - \cos(x_1' - x_2)t], \]
\[ i(\lambda, t) = 2a^2b^2[1 - \cos(x_1 - x_2)t], \]
and the parameters \( x_1', x_2', a' \), and \( b' \) are defined by \( F' = F[I(\lambda) - 1] \) with \( F' = x_1', x_2', a', \) and \( b' \). This subtle change from \( (x_1, x_2, a, b) \) to \( (x_1', x_2', a', b') \) is due to the fact that \( |G\rangle \otimes |\uparrow\rangle \) and \( |G\rangle \otimes |\downarrow\rangle \) belong to two different invariant subspaces \( H_M \) and \( H_{M-1} \). If, for simplicity, we assume that the central qubit is initially in the superposition state \( |\uparrow\rangle + |\downarrow\rangle \), we obtain from Eq. (14) the exact expression of the purity of the central qubit
\[ P = \frac{1}{4}[f(\lambda, t) + h(\lambda, t)]^2 + \frac{1}{4}[i(\lambda, t) + g(\lambda, t)]^2 + \frac{1}{2}g(\lambda, t)f(\lambda, t). \]

2. Symmetry broken phase

When \( 0 < \lambda < 1 \), the bath is in the symmetry broken phase and the ground state is the fully polarized state \( |G\rangle \)
\[ = |N/2, N/2\rangle. \]
The total Hamiltonian can be expanded in the angular momentum coupling representation

\[ |G\rangle \otimes (c_1|\uparrow\rangle + c_2|\downarrow\rangle) = c_1\frac{1}{2}(N+1), \frac{1}{2}(N+1)\right) + c_2\frac{1}{2}(N-1), \frac{1}{2}(N-1)\right),\]

where we have used the Clebsch-Gordan (CG) coefficient

\[ \left| \begin{array}{l} N \ \ N \\ 2 \ \ 2 \end{array} \right\rangle \otimes |\uparrow\rangle = \frac{\sqrt{N}}{\sqrt{N+1}} \left| \begin{array}{l} \frac{1}{2}(N+1), \frac{1}{2}(N+1) \\ \frac{1}{2}(N-1), \frac{1}{2}(N-1) \end{array} \right\rangle,\]

\[ \left| \begin{array}{l} N \ \ N \\ 2 \ \ 2 \end{array} \right\rangle \otimes |\downarrow\rangle = \frac{1}{\sqrt{N+1}} \left| \begin{array}{l} \frac{1}{2}(N+1), \frac{1}{2}(N+1) \\ \frac{1}{2}(N-1), \frac{1}{2}(N-1) \end{array} \right\rangle.\]

The total Hamiltonian (5) of the qubit and the bath can be rewritten as

\[ H = -\frac{\lambda}{N}[2J_{N+1} - 2(J_{N+1})^2 - (N+1)] - 2J_{N+1}.\]

Through the above approximation (19), both \(|N/2, N/2\rangle \otimes |\uparrow\rangle\) and \(|N/2, N/2\rangle \otimes |\downarrow\rangle\) are the eigenstate of the total Hamiltonian with the eigenenergy \(-(N+1)\) and \(2\lambda/N - (N - 1)\) respectively, and then the dynamic evolution of the two states are obvious. After a straightforward derivation, the reduced density matrix of the qubit is expressed as

\[ \rho^S(t) = |c_1|^2|\uparrow\rangle\langle\uparrow| + |c_2|^2|\downarrow\rangle\langle\downarrow| + c_1c_2^*e^{i(2\lambda N + 2\theta)}|\uparrow\rangle\langle\downarrow| \right) + H.c.,\]

and the purity of \(\rho^S(t)\) remains as unity by applying Eq. (14). It is thus proven that the qubit preserves its quantum coherence when the bath is in its symmetry broken phase \((0 < \lambda < 1)\).

**C. The coupling strength inversely proportional to the square root of the spin number of the bath (case II)**

We now turn to case II, where the coupling strength between the central qubit and the bath is inversely proportional to the square root of the spin number of the bath [7,17]. Being different from case I, the central qubit does not preserve its coherence when the bath is in the symmetry broken phase (see Fig. 3), although the purity varies also periodically in the symmetric phase (Fig. 4). Nevertheless, both the range and the pattern of its time dependence in the two phases are different from those in case I. We also remark that the purity \(P\) saturates in the symmetry broken phase when \(N\) increases, just like that in the symmetric phase of case I; while the dynamic behavior of the purity in the symmetric phase depends on \(N\) with the period being inversely proportional to \(\sqrt{N}\) approximately, as analyzed later.

**V. EQUIVALENCE TO AN ANTI-JAYNES-CUMMINGS MODEL**

In this section we show the equivalence between the above model and an anti-JC model with an intensity-
FIG. 3. Dynamic evolution of the purity \( P \) as functions of \( \lambda \) and \( t \) (case II) in the symmetric phase and symmetry broken phase. The physical meanings of \( P \) and \( \lambda \) are the same as that in Fig. 1, and \( t \in [0,1] \). Similar to Fig. 1, the gray level in this figure also represents the value of the purity. Clearly the purity varies in distinctly different manners in the two phases, which may be considered as an indication of QPT at the critical point \( \lambda = 1 \). The purity reaches a steady state in the symmetry broken phase, while the pattern of the purity will always change with \( N \) in the symmetric phase. Here we choose \( N = 1000 \).

dependent coupling strength [20]. With this observation, we can exactly solve the dynamical equation about time evolution.

A. Symmetry broken phase

When the bath is in the symmetry broken phase, our model may be recast into an anti-JC model. Actually the equivalence between the LMG model and Dike model was just studied recently [21].

In the symmetry broken phase \((0 < \lambda < 1)\), the ground state \( |N/2, N/2\rangle \) of the bath corresponds to a low excitation Fock state \( |0\rangle \) after the HP transformation. The mean photon number \( n = \langle d^\dagger d \rangle = 0 \). Hence we can directly expand the Holstein-Primakoff (HP) transformation [22] to the first-order [23]

\[
J^+_N = \sqrt{N}d, \quad J^-_N = (J^+_N)^\dagger
\]

\[
J^z_N = N/2 - d^\dagger d,
\]

and the Hamiltonian (6) can be rewritten as

\[
H_{\text{AJC}} = -k (\sigma^- d^\dagger + \sigma^+ d) + \frac{1}{2} \omega \sigma_z,
\]

where \( d^\dagger \) and \( d \) are the creation and annihilation operators of the single-mode quantized field with the frequency \( \nu \); \( -k \) is the coupling strength between the field and the two-level system; \( \omega \) is the level spacing between the two-level system; \( \sigma^z = (\sigma^+ + \sigma^-)/2 \) and \( \sigma^z = (\sigma^+ - \sigma^-)/2 \). Hence the model described by Eq. (23) is an anti-JC model (24) with \( \nu = 2(1 - \lambda) \), \( \omega = -2 \), and \( k = 2\lambda \sqrt{N} \). We now illustrate that the boson mode characterized by \( d \) and \( d^\dagger \) may be mapped from the collective spin \( J \) in a low excitation limit. Note that the different mapping ways depend on the phases of the bath because the bosonization of collective spin is essentially a mean field approach based on choice of the order parameter.

The solution \( |\Psi(t)\rangle \) of the Schrödinger equation \( i \hbar \partial_t |\Psi(t)\rangle = H_{\text{AJC}} |\Psi(t)\rangle \) can be expressed as

\[
|\Psi(t)\rangle = \sum_{n=0}^{\infty} [c_{\downarrow,N+1}(t) |\downarrow\rangle \otimes |n+1\rangle + c_{\uparrow,N}(t) |\uparrow\rangle \otimes |n\rangle],
\]

where \( n = \langle d^\dagger d \rangle \) is the mean “photon” number. A straightforward calculation determines the probability amplitudes [12]

\[
c_{\downarrow,N+1}(t) = c_{\downarrow,N+1}(0) \left[ \cos(\Omega_d t) - \frac{i}{\Omega_d} \Delta \sin(\Omega_d t) \right] + i \frac{k}{\Omega_n} \sqrt{n+1} c_{\downarrow,N}(0) \sin(\Omega_d t) \exp \left( \frac{1}{2} \frac{\Delta}{t} \right),
\]

(26)
where $\Delta = \nu + \omega$ and $\Omega_n = \sqrt{(\Delta/2)^2 + k^2(n+1)}$. After a routine calculation, we obtain the purity of the central qubit (with an initial state $|\uparrow\rangle + |\downarrow\rangle)/\sqrt{2}$) in the symmetry broken phase $(0 < \lambda < 1)$ (see Appendix A)

$$P = \frac{1}{4} \left[ 1 + \cos^2(\Omega_0 t) + \left( \frac{\Delta}{2\Omega_0} \right)^2 \sin^2(\Omega_0 t) \right]^2 + \frac{1}{4} \left( \frac{k}{\Omega_0} \right)^4 \sin^4(\Omega_0 t) + 2 \left( \frac{k}{\Omega_0} \right)^2 \sin^2(\Omega_0 t) \right].$$ \hspace{1cm} (28)

In case I ($\lambda' = \lambda/N$), the coupling strength $k = 2\lambda/\sqrt{N}$ is inversely proportional to the square root of the spin number $N$. In the large $N$ limit,

$$k^2 = \frac{4\lambda^2}{N} \ll 4\lambda^2 = \Delta^2,$$

i.e.,

$$\lim_{N \to \infty} \left( \frac{k}{\Omega_0} \right)^2 = \frac{4k^2}{\Delta^2} = 0,$$

$$\lim_{N \to \infty} \left( \frac{\Delta}{2\Omega_0} \right)^2 = \frac{\Delta^2}{\Delta^2} = 1.$$ \hspace{1cm} (30)

Hence from Eq. (28), we have $P = 1$ in large $N$ limit. This analytical analysis agrees well with Eq. (22) and Fig. 1.

Generally speaking, the quantum coherence (measured by purity) of a quantum open system would be dissipated by its bath. But when the coupling strength between the system and its bath becomes vanishingly small, and the state of the bath is properly chosen, the system will preserve all its coherence (remains in a pure state or the purity remains to be unity) during the dynamic evolution. In the thermodynamic limit, the coupling strength between the central qubit and the “radiation field” becomes vanishingly small, and the “radiation field” is in low excitation Fock state $0$). Thus the central qubit evolves under the free Hamiltonian $H_S = -s_z$, which preserves quantum coherence of the central qubit.

In case II ($\lambda' = \lambda/\sqrt{N}$), the coupling strength $k = 2\lambda$. Even in the thermodynamic limit, the interaction Hamiltonian does not vanish $(2\lambda' \sqrt{N} = 2\lambda \neq 0)$. This is why the purity of the central qubit varies in case II even when the bath is in low excitation Fock state $0$, which is the ground state of the bath in symmetry broken phase. In this case, the purity (28) can be simplified to

$$\lim_{N \to \infty} P = \frac{1}{4} \left[ \frac{32}{25} \sin^4(\sqrt{5}\lambda t) - \frac{8}{5} \sin^2(\sqrt{5}\lambda t) + 4 \right],$$ \hspace{1cm} (31)
The purity of the central qubit [with an initial state $|\uparrow\rangle + |\downarrow\rangle)/\sqrt{2}$] in the symmetric phase ($\lambda > 1$) can be determined as (see Appendix B)

$$P = \frac{1}{2} + \frac{1}{2} \left[ 1 - \left( \frac{2\lambda}{\Omega_n} \right)^2 (N-n)(n+1) \sin^2(\Omega_n t) \right]^2.$$  \hspace{1cm} (37)

In case I ($\lambda' = \lambda/N$), the purity $P$ (37) can be further simplified as

$$P = \frac{1}{2} + \frac{1}{2} \left[ 1 - \left( 1 - \frac{1}{\lambda^2} \right) \sin^2(\lambda t) \right]^2.$$  \hspace{1cm} (38)

We see from Eq. (38) that $P$ varies periodically and is independent of $N$, though the coupling strength $-2\lambda' \sqrt{N-d}$ in Eq. (33) depends on $N$, as we have seen in Fig. 1. The physics behind Eq. (38) is that the mean “photon” number of the ground state is also $N$-dependent, which counteracts with the $N$-dependent coupling strength, leading to the $N$-independent dynamical behavior of the purity $P$ in case I.

In case II ($\lambda' = \lambda/\sqrt{N}$), the purity $P$ (37) can be further simplified as

$$P = \frac{1}{2} + \frac{1}{2} \left[ 1 - \sin^2(\sqrt{N(\lambda^2-1)}t) \right]^2.$$  \hspace{1cm} (39)

Hence there does not exist an asymptotic value of the purity when $N$ increases, as observed in Figs. 3 and 4. The $N$ dependence of the purity $P$ in case II stems from the coupling strength $-2\lambda' \sqrt{N-d}$ and the $N$-dependent mean “photon” number of the ground state; the $N$ dependence of them cannot counteract with each other.

**VI. SUMMARY**

We have studied the dynamic property of a central qubit coupled to an isotropic Lipkin-Meshkov-Glick bath. Two different types of coupling strength between the central qubit and the bath are considered. In both cases, the QPT of the bath is well revealed by the dynamic behavior of the central qubit. We have found that our model is equivalent to an anti-JC model under HP transformation when the bath is in the symmetry broken phase. Especially, when the coupling strength between the central qubit and the bath is inversely proportional to the spin number of the bath, the model can be mapped into an anti-JC model with vanishing coupling strength, and the central qubit preserves its quantum coherence all the time when the bath is in its ground state. The present study not only demonstrates how the QPT influence the quantum coherence of the central qubit, but also establishes the connection between the LMG model and anti-JC model. In addition, our investigation may propose a new scenario to preserve quantum coherence of a central qubit in experimental implementation of quantum computation.

Before concluding this paper, we would like to mention three points. First, our current study is focused on a specific model of the bath and special initial state (the ground state). Nevertheless, our central result (the different behaviors of the qubit when it is coupled to the different phases of the bath) is expected to be generalized to other models of bath with long-ranged couplings, i.e., there is certain universality about our result. Similar universality can be found in short-ranged baths (see Refs. [8,24]), where the coupling to the central system impose a perturbation on the QPT controlling parameter of the bath, and the QPT of the bath at quantum critical point is signaled by a sharp decay of quantum coherence of the central system. Second, when the bath is in the symmetric phase ($\lambda > 1$), the choice of initial state (spontaneous symmetry breaking in the bath or not) would have rather large effects on the behavior of the central qubit [6]. We here do not address the spontaneous symmetry breaking of the bath (when it is in the symmetric phase) in our current study. A detailed study on spontaneous symmetry breaking of the model is expected to be done in the future. Moreover, the conjunction between our central result and the main result in Ref. [6] “universal limit to quantum coherence due to spontaneous symmetry breaking” is also interesting and worth to be studied. Third, finite-temperature extension of “QPT-induced decoherence” (Loschmidt echo decay) has been studied in Ref. [25]. Following the same way, it is expected that our result can even be generalized to low but finite temperature.

**APPENDIX A: DYNAMICS OF PURITY IN THE SYMMETRY BROKEN PHASE ($0 < \lambda < 1$)**

For the anti-JC Hamiltonian (24), the time evolution of a initial state $|\Psi(0)\rangle=(|\uparrow\rangle+|\downarrow\rangle)/\sqrt{2} \otimes |0\rangle$ can be expressed as

$$|\Psi(t)\rangle = \frac{ik}{\sqrt{2}\Omega_0} \sin(\Omega_0 t) \exp \left( \frac{i\Delta}{2} |\downarrow\rangle \otimes |1\rangle \right) + \left[ \cos(\Omega_0 t) + \frac{i\Delta}{2\Omega_0} \sin(\Omega_0 t) \right] \exp \left( -\frac{i\Delta}{2} |\downarrow\rangle \otimes |0\rangle \right) + |\uparrow\rangle \otimes |0\rangle.$$  \hspace{1cm} (A1)

The reduced density matrix $\rho(t)$ (Eq. (13)) of the system is then found to be
$\rho^\delta(t) = \text{Tr}_B[|\Psi(t)\rangle\langle\Psi(t)|$

\begin{align*}
&= \frac{1}{2}\left[1 + \left(\frac{k}{\Omega_0}\right)^2 \sin^2(\Omega_0 t)\right] |\uparrow\rangle\langle\uparrow| + \frac{1}{2} \left[\cos(\Omega_0 t) + \Delta \frac{\sin^2(\Omega_0 t)}{2}\right] |\downarrow\rangle\langle\downarrow| + \frac{1}{2} \left[\cos(\Omega_0 t) - \Delta \frac{\sin^2(\Omega_0 t)}{2}\right] |\uparrow\rangle\langle\downarrow| + \frac{1}{2} \left[\cos(\Omega_0 t) + \Delta \frac{\sin^2(\Omega_0 t)}{2}\right] |\downarrow\rangle\langle\uparrow|
\end{align*}

(A2)

Applying Eq. (14), we obtain the purity $P$ [Eq. (28)] of the central qubit

\begin{align*}
P &= \frac{1}{4} \left[1 + \cos^2(\Omega_0 t) + \left(\frac{\Delta}{2 \Omega_0}\right)^2 \sin^2(\Omega_0 t)\right]^2 \\
&+ \left[\frac{k}{\Omega_0}\right]^4 \left[\sin^2(\Omega_0 t) + 2 \left(\frac{k}{\Omega_0}\right)^2 \sin^2(\Omega_0 t)\right].
\end{align*}

(A3)

**APPENDIX B: DYNAMICS OF PURITY IN THE SYMMETRIC PHASE ($\lambda > 1$)**

For a generalized anti-JC Hamiltonian [Eq. (33)], the time evolution of an initial state $|\Phi(0)\rangle = (|\uparrow\rangle + |\downarrow\rangle)/\sqrt{2} \otimes |n\rangle$ can be expressed as

\begin{align*}
|\Phi(t)\rangle &= \frac{1}{2\sqrt{2}} \left\{ \cos(\Omega_{n-1}' t) - \frac{\Xi_n}{\Omega_{n-1}'} \sin(\Omega_{n-1}' t) \right\} |\uparrow\rangle \otimes |n\rangle \times \exp(-i A_{n-1} t) |\uparrow\rangle \otimes |n+1\rangle \\
&+ \frac{1}{\sqrt{2}} \left\{ \cos(\Omega_{n-1}' t) + \frac{\Xi_n}{\Omega_{n-1}'} \sin(\Omega_{n-1}' t) \right\} |\downarrow\rangle \otimes |n\rangle \times \exp(-i B_{n-1} t) |\downarrow\rangle \otimes |n-1\rangle \times \exp(-i A_{n-1} t) |\downarrow\rangle \otimes |n+1\rangle.
\end{align*}

(B1)

In the large $N$ limit, the reduced density matrix $\rho^\delta(t)$ [Eq. (13)] of the central qubit is derived as

\begin{align*}
\rho^\delta(t) &= \text{Tr}_B[|\Phi(t)\rangle\langle\Phi(t)|$

\begin{align*}
&= \frac{1}{2} |\uparrow\rangle\langle\uparrow| + \frac{1}{2} |\downarrow\rangle\langle\downarrow| + \frac{1}{2} \exp[-i(A_n - B_n)t] \\
&\times \left\{ \cos(\Omega_{n-1}' t) - \frac{\lambda}{\Omega_{n-1}'} \sin(\Omega_{n-1}' t) \right\}^2 |\uparrow\rangle\langle\downarrow| + \frac{1}{2} \exp[-i(A_n - B_n)t] \\
&\times \left\{ \cos(\Omega_{n-1}' t) + \frac{\lambda}{\Omega_{n-1}'} \sin(\Omega_{n-1}' t) \right\}^2 |\downarrow\rangle\langle\uparrow|. 
\end{align*}

(B2)

Using Eq. (14), we obtain the purity $P$ [Eq. (37)] of the central qubit

\begin{align*}
P &= \frac{1}{2} + \frac{1}{2} \left[1 - \frac{(2\lambda)^2}{\Omega_{n-1}^2} (N-n)(n+1) \sin^2(\Omega_{n-1}' t) \right]^2.
\end{align*}

(B3)
