N-lobe versus C-lobe complexation of bismuth by human transferrin

Hongzhe SUN*, Hongyan LI†, Anne B. MASON†, Robert C. WOODWORTH‡ and Peter J. SADLER*†
*Department of Chemistry, University of Edinburgh, Edinburgh EH9 3JJ, U.K., and †Department of Biochemistry, University of Vermont College of Medicine, Burlington, VT 05405, U.S.A.

Interactions of recombinant N-lobe of human serum transferrin (hTF/2N) with Bi³⁺, a metal ion widely used in medicine, have been investigated by both UV and NMR spectroscopy. The bicarbonate-independent stability constant for Bi³⁺ binding (K*) to hTF/2N was determined to be log K* 18.9 ± 0.2 in 5 mM bicarbonate/10 mM Hepes buffer at 310 K, pH 7.4. The presence of Fe³⁺ in the C-lobe of intact hTF perturbed Bi³⁺ binding to the N-lobe, whereas binding of Bi³⁺ to the C-lobe was unaffected by the presence of Fe³⁺ in the N-lobe. Reactions of Bi³⁺ (as bismuth nitritolriacetate or ranitidine bismuth citrate) with hTF/2N in solutions containing 10 mM bicarbonate induced specific changes to high-field ¹H-NMR peaks. The ¹H co-ordination shifts induced by Bi³⁺ were similar to those induced by Fe³⁺ and Ga³⁺, suggesting that Bi³⁺ binding causes similar structural changes to those induced by hTF/2N. ¹³C-NMR data showed that carbonate binds to hTF/2N concomitantly with Bi³⁺.

Key words: metal binding, NMR spectroscopy, protein conformation, stability constant, serum protein.

INTRODUCTION

Transferrin belongs to a class of 80 kDa monomeric glycoproteins, which are functional in iron transport and detoxification in vertebrates [1,2]. It has two structurally similar lobes, each of approx. 40 kDa, linked by a short peptide and each lobe contains an interdomain high-affinity metal-binding site [3,4]. The X-ray crystal structures of rabbit serum transferrin [5,6], the related protein diferric lactoferrin [7,8] and monoferric human transferrin [9] show that Fe³⁺ in each lobe has approx. octahedral co-ordination, consisting of two oxygens from two tyrosine side-chains, one nitrogen from histidine, one oxygen from aspartate and two oxygens from a bidentate synergistic anion, carbonate. An important feature that has emerged from X-ray studies of transferrin is that iron induces a conformational change from a lobe-open (apo-form) to a lobe-closed (holo-form). Only the holo-form (metal loaded in both lobes), and not the apo-form, binds strongly to the cell receptor and is taken up. Apo-hTF was purchased from Sigma (catalogue no: T0519). hTF/2N was expressed in the methylothrophic yeast, Pichia pastoris, by placing the hTF/2N cDNA under the control of the methanol-inducible alcohol oxidase promoter, and purified as described previously [17]. The Fe³⁺ was removed by additions of metal-removal buffer [1 mM nitritolriacetate (NTA)/1 mM EDTA/0.5 M sodium acetate (pH 4.9)] [18], followed by ultrafiltration three times (1 h each time) in a Centricon 10 (Amicon, Stonehouse, Gloucestershire, U.K.). Finally, the protein was washed four times with 0.1 M KCl to remove low-molecular-mass impurities via ultrafiltration (Centricon 10). For apo-hTF, a similar procedure was used to remove low-molecular-mass impurities (Centricon 30). Monoferric transferrins (selective loading of Fe³⁺ in either the N- or C-lobe of transferrin) were prepared as described previously [19]. Use of the reported procedure for selective Fe³⁺ loading of the N-lobe [using Fe(NH₂)₆(SO₄)₂] appears to provide > 80% selective N-lobe loading [20], although in NMR experiments we have found that

EXPERIMENTAL

Materials

Apo-hTF was purchased from Sigma (catalogue no: T0519). hTF/2N was expressed in the methylothrophic yeast, Pichia pastoris, by placing the hTF/2N cDNA under the control of the methanol-inducible alcohol oxidase promoter, and purified as described previously [17]. The Fe³⁺ was removed by additions of metal-removal buffer [1 mM nitritolriacetate (NTA)/1 mM EDTA/0.5 M sodium acetate (pH 4.9)] [18], followed by ultrafiltration three times (1 h each time) in a Centricon 10 (Amicon, Stonehouse, Gloucestershire, U.K.). Finally, the protein was washed four times with 0.1 M KCl to remove low-molecular-mass impurities via ultrafiltration (Centricon 10). For apo-hTF, a similar procedure was used to remove low-molecular-mass impurities (Centricon 30). Monoferric transferrins (selective loading of Fe³⁺ in either the N- or C-lobe of transferrin) were prepared as described previously [19]. Use of the reported procedure for selective Fe³⁺ loading of the N-lobe [using Fe(NH₂)₆(SO₄)₂] appears to provide > 80% selective N-lobe loading [20], although in NMR experiments we have found that
the selectivity is slightly lower [21]. Crystalline Bi-NTA was synthesized using a procedure in the literature [22] and had a satisfactory elemental analysis. Ranitidine bismuth citrate (RBC) was supplied by Glaxo Wellcome (Stevenage, Herts., U.K.). NaHCO₃, KCl, H₃NTA and Hapes were purchased from Aldrich (Milwaukee, WI, U.S.A) and NaH¹³CO₃ (99 %, enriched-¹³C) was from MSD Isotopes (Montreal, Canada).

Preparation of NMR samples
To allow ¹H–¹H exchange, apo-hTF/2N was dissolved in 0.1 M KCl in ¹H₂O, and after adjustment of the pH* (pH meter reading for ¹H₂O solution) to 7.8, this was left for 4 h at ambient temperature. After freeze-drying, the sample was redissolved in ¹H₂O containing 10 mM NaHCO₃. The pH* was then readjusted to 7.80 ± 0.05, when necessary, using NaOH and ¹HCl (0.2 M). The pH* values of NMR solutions were recorded before and after NMR measurements.

Samples for electronic absorption spectroscopy
These were prepared by diluting aliquots of stock apo-hTF/2N or monoferric transferrin solutions to approx. 10⁻⁵ M with 10 mM Hapes buffer, pH 7.4. The concentrations were determined spectrophotometrically on the basis of εmax 38,600 and 103,000 M⁻¹·cm⁻¹ for hTF/2N and monoferric transferrins respectively [17,23]. Immediately before addition of Bi³⁺, an aliquot of a concentrated solution of NaHCO₃ (0.25 M) was added to give 5 mM HCO₃⁻. The spectrum of the apo-hTF/2N solution (containing 5 mM bicarbonate) was recorded after equilibration at 310 K for 10 min. Aliquots of the stock solution of bismuth (usually 5–20 μl of Bi-NTA solution) were then added to the apo-hTF/2N cuvette and spectra were recorded after at least 0.5 h equilibration at 310 K. A similar procedure was used for titration of monoferric transferrins with Bi-NTA.

NMR spectroscopy
¹H-NMR spectra were recorded on Bruker DMX 500 or Varian Unity 600 spectrometers at 500 and 600 MHz respectively. Spectra were acquired using 0.7 ml of solution in 5-mm tubes (0.9 mM hTF/2N) at 310 K, and 400–1200 transients, 6 μs (50°) pulses, recycle time of 2 s, 16 K data points and water suppression via pre-saturation. The chemical shift reference compound was dioxane via endogenous formate (8.465 p.p.m., pH* > 7), which was always present in our samples as a minor impurity. Resolution enhancement of the spectra was achieved by processing the free induction decays with a combination of unshifted sinebell and exponential functions (line broadening of 1.5–5 Hz) on a Silicon Graphics computer using Varian VNMR software (VNMR, 4.3) and Xwin NMR (2.0). Two-dimensional TOCSY and NOESY spectra (mixing times 60 and 50 ms respectively) of hTF/2N at pH* 7.25 were acquired using 2 K data points in the f2 dimension, acquisition time 0.12 s, 48 scans and 256 increments in the f1 dimension, in a total time of 14 h. Unshifted Gaussian functions were used in both dimensions for processing two-dimensional spectra.

The ¹H-decoupled ¹³C spectrum was recorded at 310 K on the Bruker DMX 500 MHz NMR spectrometer equipped with a 5-mm broad-band probe at a resonance frequency 125 MHz. Typically 20000–40000 transients were collected using a pulse-width of 8 μs (50°), a relaxation delay of 2 s and 16 K data points. The spectra were processed using an exponential function (8–10 Hz) before Fourier transformation.

RESULTS

Electronic absorption spectroscopy
The complexation of metal ions to the phenolate groups of the tyrosine residues in the specific metal-binding sites of apo-transferrin led to the production of two new absorption bands at 241 and 295 nm [2]. These new bands are readily apparent in difference UV spectra of metal-containing transferrin and apo-hTF.

The recombinant N-lobe of transferrin (hTF/2N) was titrated with Bi-NTA (x = 1.10), and the absorbance at 241 nm was monitored. The UV difference spectra and titration curves are shown in Figures 1 and 2 respectively. For the NTA:Bi = 1:1 curve, Δε increases linearly with an increase in the ratio of Bi:hTF/2N, and from the initial slope of the curve the molar absorption coefficient of Bi-hTF/2N was obtained as 22000 M⁻¹·cm⁻¹. Owing to NTA competition, the titration curve for NTA:Bi = 10:1 levelled off, and Bi³⁺ was loaded only partially into the metal-binding site of hTF/2N. This curve was used to calculate the stability constant of Bi-hTF/2N.

The stability constant determination was based on the basis of the competition reaction of NTA and hTF/2N with Bi³⁺, and the following equations were used:

Bi-NTA + hTF/2N = Bi-hTF/2N + NTA

Kₙ = [Bi-hTF/2N][NTA]/[Bi-NTA][hTF/2N] (1)

Bi³⁺ + hTF/2N = Bi-hTF/2N

Kₛ = [Bi-hTF/2N][Bi³⁺][hTF/2N] = Kₛ[NTA]Kₙ (2)

Kₛ was obtained from the Hill plot:

1/Y = 1 + 1/Kₛ[NTA]/[Bi-NTA] (3)

where Y = [Bi-hTF/2N]/[hTF/2N]_total, and the concentration of Bi-hTF/2N was calculated by assuming that full loading of

Figure 1  UV difference spectra for Bi³⁺ binding to hTF/2N

Bi-NTA (0.2, 0.4, 0.6, 0.8, 1.0 and 1.4 molar equivalents) was added to 1.09 x 10⁻⁵ M recombinant hTF/2N in 10 mM Hapes buffer containing 5 mM bicarbonate, at 310 K, pH 7.4. The two absorption bands at 241 and 295 nm are indicative of Bi³⁺ binding to the specific binding site of hTF/2N.
hTF/2N with Bi\(^{3+}\) gives a molar absorption coefficient of 22000 M\(^{-1}\)·cm\(^{-1}\). By plotting 1/\(Y\) versus [NTA]/[Bi-NTA] (Figure 2 insert), \(\log K\) was obtained from the slope as 1.40 ± 0.2. The reported (log) stability constant of Bi-NTA is 17.75 [24], therefore the stability constant of Bi-hTF/2N is \(\log K = 19.15 ± 0.2\) (in 10 mM Hapes and 5 mM bicarbonate at 310 K, pH 7.4). The bicarbonate-independent binding constant (log \(K^0\)) can be calculated to be 18.9 ± 0.2 using the procedure reported previously [25].

The effect of bound Fe\(^{3+}\) on the uptake of Bi\(^{3+}\) into either the N- or C-lobe of intact hTF was studied. Apotransferrin was selectively loaded with Fe\(^{3+}\) in the C- or N-lobe and then titrated with Bi\(^{3+}\). The results are shown in Figure 3. When Bi\(^{3+}\) (as Bi-NTA) binds to the vacant C-terminal site of monoferric transferrin with Fe\(^{3+}\) in the N-lobe (Fe\(_N\)-hTF), the initial slope of the curve (\(\Delta \varepsilon = 21\,740\) M\(^{-1}\)·cm\(^{-1}\)) is close to that observed for apo-transferrin (\(\Delta \varepsilon = 21\,900\) M\(^{-1}\)·cm\(^{-1}\)) [13]. In contrast, binding of Bi\(^{3+}\) to the vacant N-terminal site of monoferric transferrin with Fe\(^{3+}\) in the C lobe (Fe\(_C\)-hTF) gave a much lower molar absorption coefficient of 12600 M\(^{-1}\)·cm\(^{-1}\). For hTF/2N, the titration curve is almost identical with that of N-terminal monoferric transferrin (Fe\(_N\)-hTF) with a molar absorption coefficient of 22000 M\(^{-1}\)·cm\(^{-1}\).

**Ligand competition**

Competition between hTF/2N and citrate for Bi\(^{3+}\) binding was investigated. Large excesses of citrate removed Bi\(^{3+}\) from the binding site. The \(\Delta \varepsilon\) value appeared to decrease almost linearly with increase of citrate concentration (Figure 4). From the linear range, it was calculated that an approx. 125-fold molar excess of citrate (1.36 mM) is required to remove Bi\(^{3+}\) from hTF/2N completely. However, for the intact protein Bi\(_i\)-hTF, such an excess of citrate appeared to remove only about half of the bound Bi\(^{3+}\) from the protein.

**\(^{13}\)C-NMR analysis**

These experiments were carried out to investigate whether the binding of Bi\(^{3+}\) to hTF/2N also involves concomitant binding of (bi)carbonate as a synergistic anion. Proton-decoupled \(^{13}\)C-NMR spectra of a solution containing hTF/2N and 10 mM \(^{13}\)C-enriched bicarbonate (> 99 %, in \(^{13}\)C) in the absence or presence of Bi\(^{3+}\) are shown in Figure 5. In the absence of Bi\(^{3+}\), the sharp signal at 161.1 p.p.m. can be assigned to free bicarbonate, and the broad envelope at 168–182 p.p.m. to backbone and side chain carbonyl groups of the protein. After addition of 1.0 molar equivalent of Bi\(^{3+}\) (as Bi-NTA), a new peak at 165.7 p.p.m. is observed, which can be assigned to bound (bi)carbonate [13,26,27].

**\(^{1}\)H-NMR analysis**

These experiments were carried out to investigate bismuth-induced structural changes in hTF/2N. Additions of Bi\(^{3+}\) were made (0.6 and 1.0 molar equivalent of [Bi-NTA]) to hTF/2N in the presence of 10 mM bicarbonate. Specific resonances in both high- and low-field regions of the spectrum progressively disappeared and new resonances appeared, indicative of strong binding of Bi\(^{3+}\) and slow exchange between apo-hTF/2N and Bi-hTF/2N on the \(^{1}\)H-NMR chemical shift time scale. Peaks A, B...
peak C). Peaks A (0.126 to low-field) and B (0.059 p.p.m. to low-field), and C (0.100 p.p.m. to high-field) became visible. The two-dimensional spectra are well resolved in the high-field region. Peaks A (0.126 p.p.m.) and B (0.059 p.p.m.) have previously been assigned as Ile\textsuperscript{\(\gamma\)}-CH\(_3\) and Leu\textsuperscript{\(\delta\)}-CH\(_3\) respectively, on the basis of ring-current calculations and with the aid of mutation of Trp\textsuperscript{\(13\)} [28,29]. Two-dimensional TOCSY and NOESY spectra of apo-hTF and hTF\textsubscript{2N} were also recorded (results not shown). Analysis of most of the resonances was impossible due to the large number of overlapping cross-peaks. However, the two-dimensional spectra are well resolved in the high-field region. Peaks A (\(\gamma\)-CH\(_3\) of Ile\textsuperscript{\(13\)} and B (\(\delta\)-CH\(_3\) of Leu\textsuperscript{\(13\)}) had associated cross-peaks at 0.100, 0.400, 0.830 and 1.378 p.p.m., and 0.413, 0.543, 1.143 and 1.457 p.p.m. respectively, which are consistent with intramolecular nuclear Overhauser effects for isoleucine and leucine spin systems. Similar patterns of cross-peaks for A and A\textsuperscript{\(\gamma\)}, B and B\textsuperscript{\(\delta\)}, and C and C\textsuperscript{\(\gamma\)} in the NOESY spectrum of this aliphatic region strongly suggested that A\textsuperscript{\(\gamma\)} is the bound form of A, and B\textsuperscript{\(\delta\)} and C\textsuperscript{\(\gamma\)} are the bound forms of B and C respectively. With 1.0 molar equivalent of Bi\textsuperscript{3+} present, the new resonances increased their intensities further, while the resonances for hTF/2N disappeared almost completely. Notable shifts induced by Bi\textsuperscript{3+} binding are those for peak A, 0.100 p.p.m. to high-field, peak B, 0.059 p.p.m. to low-field, and peak C, 0.126 to low-field (Table 1 and Figure 7).

In the histidine C2H region (Figure 8), a notable change is the appearance of peaks at 7.613 and 7.626 p.p.m. (J'). peaks D, G, H, and I decreased in intensity, and new peaks K', H', and I' also appeared after addition of Bi\textsuperscript{3+}. Peaks H' and I' appeared to undergo low-field shifts of 0.085 and 0.076 p.p.m. respectively on addition of 1.0 molar equivalent of Bi\textsuperscript{3+}, although again, ambiguous correlations between peaks cannot be made. A sharp resonance at 5.995 p.p.m., which is sensitive to oxalate and insensitive to bicarbonate, decreased in intensity and appeared to shift to 6.004 p.p.m. (broad peak) when 1.0 molar equivalent of Bi\textsuperscript{3+} was added (results not shown).

Changes were also observed in the region 1.9–2.3 p.p.m., which contains resonances for Met-CH\(_3\) and carbohydrate (results not shown). Resonances at 2.096, 2.074 and 2.059 p.p.m. have not been observed previously for hTF/2N samples, and are thus assigned to the two carbohydrate residues that are attached to the protein in the yeast expression system [17]. The presence of carbohydrate was also confirmed by the presence of intense resonances from 3.0 to 4.5 p.p.m. (results not shown). Peaks at 2.218, 2.165, 2.143 and 1.967 p.p.m. have been assigned previously [30] to S-CH\(_3\) of Met\textsuperscript{\(23\)}, Met\textsuperscript{\(24\)}, Met\textsuperscript{\(25\)} and Met\textsuperscript{\(29\)}/Met\textsuperscript{\(26\)} respectively. Upon addition of 0.6 molar equivalent of Bi\textsuperscript{3+}, the broad resonances assigned to Met\textsuperscript{\(23\)}/Met\textsuperscript{\(24\)} decreased in intensity and a broad shoulder appeared at 1.982 p.p.m.. On addition of 1.0 molar equivalent of Bi\textsuperscript{3+}, the latter peak increased in intensity further, and that for Met\textsuperscript{\(23\)}/Met\textsuperscript{\(24\)} disappeared. Similarly, the Met\textsuperscript{\(25\)} resonance also disappeared, whereas peaks for Met\textsuperscript{\(24\)} and those for carbohydrate remained unchanged.

hTF/2N was also titrated with the new bismuth anti-ulcer agent, RBC. This gave rise to NMR spectra identical with those obtained with Bi-NTA in the presence of 10 mM bicarbonate at pH* of 7.8 (results not shown), apart from peaks that were due to added ligands.

$^*$Co-ordination shift; †pH* at 8.8; ‡pH* 7.8; for these data, hTF/2N was expressed in the methylotrophic yeast P. pastoris and contained two carbohydrate residues that are not present in the N-lobe of the intact serum protein [17].

In order to compare $^1$H chemical shifts induced by Bi$^{3+}$ with those induced by Fe$^{3+}$, a titration of hTF/2N with Fe$^{3+}$ [added as Fe(NTA)$_2$] in the presence of 10 mM bicarbonate at pH* 7.8 was also carried out. Although $^1$H-NMR spectra were broadened upon addition of Fe$^{3+}$, owing to the paramagnetic effects of bound high-spin Fe$^{3+}$, new peaks in the high-field (Figure 6B) and methionine regions were still observable. The chemical shifts induced by Fe$^{3+}$ appeared to be almost identical with those induced by Bi$^{3+}$ in these regions, indicative of a similar binding mode and similar structural changes. Notable co-ordination shifts induced by Fe$^{3+}$ complexation are those of peak A (Ile$^{132}$), 0.222 p.p.m. to high field, peak B (Leu$^{122}$),
DISCUSSION

Bi\(^{3+}\) [ionic radius 1.03 Å (0.103 nm)] is a much larger ion than Fe\(^{3+}\) [radius 0.65 Å (0.065 nm), high-spin state], but binds to human transferrin almost as strongly as Fe\(^{3+}\), a feature which can be correlated with its high acidity (low pK\(_a\) of bound H\(_2\)O) [24].

In the present work we have determined the binding constant for Bi\(^{3+}\) binding to hTF/2N, log \(K^*\) [25] of 18.9 ± 0.2. Thus Bi\(^{3+}\) binds to the N-lobe almost as strongly as to the intact protein (log \(K^*_a\) = 19.4, log \(K^*_s\) = 18.6 [13]). This appears to be the first determination of a binding constant for any metal ion for the isolated N-lobe.

The larger stability constant for Bi\(^{3+}\) binding to hTF can be associated with Bi\(^{3+}\) uptake by the C-lobe, since this lobe has been shown by two-dimensional \(^1\)H- and \(^{13}\)C-NMR studies of Met-\(\epsilon\)\(^{13}\)C-labelled protein to take up Bi\(^{3+}\) preferentially [21]. Other metal ions, such as Fe\(^{3+}\), Zn\(^{2+}\) and Sm\(^{3+}\), also show preferential binding to the C-lobe, although Ni\(^{2+}\) and Al\(^{3+}\), under certain conditions, are taken up preferentially by the N-lobe of hTF [18,31]. The specificity of uptake can be influenced by the initial ligand complexed to the metal ion, the synergistic anion and the pH. Since the transferrin receptor binds much more strongly to transferrin loaded with two Fe\(^{3+}\) ions, it is interesting to examine possible communication between the N- and C-lobes.

In this work, we have investigated the effect of Fe\(^{3+}\) loading of the N- or C-lobe on the binding of Bi\(^{3+}\) to the other lobe. With Fe\(^{3+}\) in the N-lobe of hTF (Fe\(_3\)-hTF), Bi\(^{3+}\) binds to the C-lobe as strongly as it does in the apoprotein (N-lobe vacant), whereas the binding of Bi\(^{3+}\) to the N-lobe of hTF with Fe\(^{3+}\) in the C-lobe (Fe\(_3\)-hTF) is much weaker than binding to the isolated N-lobe. Calorimetric studies of the binding of Fe\(^{3+}\) to ovotransferrin have shown that binding to one lobe is communicated to the other [32], and \(^{13}\)C-NMR studies have suggested that Ga\(^{3+}\) binding to the N-lobe of hTF is communicated to the C-lobe [30]. Previous reports have shown that Al\(^{3+}\), Zn\(^{2+}\), Nd\(^{3+}\) and Sm\(^{3+}\) also have a higher affinity for the C-lobe compared with the N-lobe [33–35].

Since a large excess of citrate is required to remove significant amounts of Bi\(^{3+}\) from transferrin (Figure 4), it seems likely that citrate would not be a major competitor for Bi\(^{3+}\) in blood plasma (citrate concentration \(\approx\) 100 \(\mu\)M [36]; hTF: citrate ratio approx. 1:3). Comparison of the curves in Figure 4 suggests that citrate is much less effective in removing Bi\(^{3+}\) from the C-lobe compared with the N-lobe. In blood, hTF is normally saturated to a level of only \(\approx\) 30% with Fe\(^{3+}\), which occupies the N-lobe [16], although it has been suggested that this switch from C- to N-lobe preference may be related to the presence of receptor protein [37].

In general, the \(^1\)H-NMR spectrum of hTF/2N consists of a large number of broad overlapping resonances. However, reasonable assignments have been proposed previously for several peaks in the high-field region, specifically for Leu\(^{35}\) and Ile\(^{36}\), which are above and below Trp\(^{19.4}\), log \(K\) for Bi\(^{3+}\) binding to hTF/2N has been shown previously [29] that oxalate binding causes shifts of the hTF/2N resonance at 5.995 p.p.m. No such shifts were observed in this work with bicarbonate as the synergistic anion, which may be indicative of a different binding mode or affinity for these two anions before addition of metal.

The shift changes for the Met-S-\(\epsilon\)-CH\(_3\) resonances of hTF/2N
on Bi\(^{3+}\) binding are similar to those observed previously [29] for Ga\(^{3+}\). The methionine residues are well dispersed in the protein’s structure, and their behaviour is probably a good indication of the similar binding mode of these metal ions. In view of this it will be interesting to investigate the binding of Bi\(^{3+}\)-transferrin to the transferrin receptor. Such work is in progress.

Our studies show that Bi\(^{3+}\) in the form of the anti-ulcer drug, RBC, is also readily transferred to hTF/2N, forming the same transferrin adducts as for Bi-NTA. Citrate is readily displaced from Bi\(^{3+}\) by hTF/2N and could act as a transfer agent in blood plasma. Further experiments on blood plasma are required to establish whether this is the case.

Conclusion

We have made the first determination of a stability constant for metal binding to recombinant N-lobe of human transferrin. The metal ion used, Bi\(^{3+}\), is important because it forms the basis of widely used anti-ulcer drugs. Bi\(^{3+}\) binds strongly to hTF/2N (log \(K^\text{st} = 18.9 \pm 0.2\) in 5 mM bicarbonate/10 mM Hepes buffer at 310 K, pH 7.4). The presence of bound synergistic anion (CO\(_3\)\(^2-\)) was confirmed by \(^{1}C\)- and \(^{1}H\)-NMR studies, and suggested that the conformational changes induced by Bi\(^{3+}\) binding are similar to those induced by Fe\(^{3+}\), Al\(^{3+}\) and Ga\(^{3+}\).

Studies on hTF suggested that occupation of the C-lobe by Fe\(^{3+}\) perturbs Bi\(^{3+}\) binding to the N-lobe, but Fe\(^{3+}\) occupation of the N-lobe has little effect on Bi\(^{3+}\) binding to the C-lobe. Future work will focus on an investigation of the biological activity of bismuth transferrin.

We thank the Glaxo Wellcome p.l.c., Engineering and Physical Sciences Research Council (EPSRC), Biotechnology and Biological Sciences Research Council (BBSRC), and United States Public Health Service (USPHS) (Grant R01DK21739) for their support, and University of London Intercollegiate Research Service (ULIRS) Biomedical NMR Service at Birkbeck College and the Biomedical NMR centre at the National Institute of Medical Research (Mill Hill, London) for the provision of NMR facilities. We are grateful to the Committee of Vice-Chancellors and Principals of the Universities of the United Kingdom for an Overseas Research Student Award (to H.L.).
