Background: Congenital myopathies (CMs) are a genetically and clinically heterogeneous group of neuromuscular disorders. Historically, the congenital myopathies are classified according to muscle biopsy findings – Rods (Nemaline myopathy) (NM), cores (central core disease and multiminicore disease) (Core and MMC), central nuclei (centronuclear/ myotubular myopathy)(CNM) , and selective hypotrophy of type 1 fibres (congenital fibre type disproportion CFD). Over twenty genes have been implicated in CMs. The overlapping clinical presentations among different histopathological findings and different mutations poses major diagnostic challenge.

Objective: We investigated the characteristics of children with congenital myopathies in Hong Kong.

Patients and methods: We identified all patients with a confirmed diagnosis of CM between 2012-March 2015. Their clinical presentation , muscle biopsy, muscle MRI and genetic analysis results were evaluated.

Results:

Patients:

Total 15 patients have been diagnosed to have CM. Nine were males (60%), 6 were female (40%).

Genetic findings:

(1) A genetic diagnosis could be established in 11 (73%) out of 15 patients. Among those 11 patients, 4 (36%) were mutated in *RYR1*, 3 (27%) in *ACTA1*, 2 (18%) in *KLHL40* , 1 (9%) in *MTM1* and 1 (9%) in *DNM2*. A total of 13 mutation were identified.

(2) The missense *RYR1* mutation (c.3523G>A) was found in 2 patients, and the missense *KLHL40* mutation (c.1516A>C) was found in another 2 patients, suggesting that these variants could probably be the hot spots mutation among Chinese patients.

(3) Pathological heterogeneity caused by *RYR1* mutation is shown in our 4 patients showing different findings including nemaline rods, central cores, multiminicores, or type 1 fibre predominance.

Histopathological features:

(1) Muscle biopsy evaluation were available in all 15 patients. Nemaline myopathy were the most frequent histopathological diagnosis, in 5 patients (33%), followed by core myopathy, in 4 patients (26%), centronuclear myopathy in 2 patients (13%), congenital fibre type disproportion in 2 patients (13%), zebra bodies in 1 (6.7%) patient and type 1 predominance in 1 (6.7 %) patient.

(2) Genetic heterogeneity is illustrated in our patients with nemaline myopathy. Amongst the 5 patients, 1 had *RYR1,* 2 had *ACTA1* and 2 had *KLHL40* mutation.

Clinical features:

(1) Of the 15 patients, 9 (60%) had age of onset at birth or before one month, 3 (20%) between 1 and 12 months, and 3 (20%) between 1 and 5 years. Out of the 9 patients with early neonatal presentation, 3/9 (33%) patients died before 13 months.

(2) The functional abilities varied from very severe weakness required tube feeding and ventilation support , to intermediate functional abilities with possible independent sitting , to mild limb girdle weakness only.

(3) *ACTA1, KLHL40, DNM2* and *MTM1* mutations are associated with severe presentation with early neonatal onset .

(4) *RYR1* mutations are associated with a milder phenotype with all the affected patients maintain independent walking

Muscle imaging:

Selective muscle involvement with Rectus Femoris sparing provides helpful clues to a possible underlying RYR1 mutation.

(a &b). Electron microscopy (EM) of muscle biopsies of patients 4 & 5 with nemaline myopathy due to *KLHL40* mutation with roundish rods; (c&d). Electron microscopy of muscle biopsies of patient 2 & 3 with nemaline myopathy due to *ACTA1* mutation; (e) Muscle biopsy of patient 12 with central core disease having rods shown on EM; (f) A zebra body is noted on the EM of patient 1 with *ACTA1*-related congenital myopathy when the muscle biopsy was performed at 1.5 month old; (g & h) Muscle biopsy of patient 13 with multi-minicores on the EM; (i & j) Muscle biopsy of patient 8 with multi-minicore disease due to *RYR1* mutation showing uneven staining with SDH in some fibres and EM shows a large minicore with excess Z-line material and myofilament disruption; (k & l) Muscle biopsy of patient 7 with central core myopathy due to *RYR1* mutation with NADH shows numerous cores and EM shows a central core in the centre with disrupted Z-line. (m & n) Muscle biopsy of patient 11 with centronuclear myopathy due to *DNM2* mutation. Central nuclei are seen in some fibres (H&E) and no radiating strands are noted from the central nuclei (NADH).
